In habit the plant somewhat resembles *C. barbatum*, but its leaves are entirely green, or with a very obscure tinge of dark green on a lighter green ground. The flowers are very quaint in structure, the upper sepal white with greenish rays at the base, petals white, tinged with rose at the tips, and spotted with red, labellum white and crimson. A drawing made from a flower which opened on the journey will be on view, but under cultivation it is expected that the plant will become much more beautiful.

MR. J. C. STEVENS will include the above in his SALE by AUCTION, at his Great Rooms, 38, King Street, Covent Garden, W.C., on THURSDAY NEXT, October 6. On view morning of Sale, and Catalogues had.

NEW MAIDENHAIR.

ADIANTUM CAPILLUS-VENERIS IMBRICATUM
(DICKSONS)

This splendid NEW FERN is a decided acquisition, being quite equal in appearance to A. Farleyense, with the hardness of A. Capillus-veneris.

Full particulars, with price, on application.

DICKSONS (LIMITED), THE NURSERIES, CHESTER.

VICTOR POTATOS
(SHARPE'S).

This favourite first early Potato, suitable for any Garden, indispensable for Forcing and Early Borders, and likely to take the first rank amongst first earlies for market use. Quality and yield all that could be desired. One well known market grower has this year had a yield of 15 tons per acre on a large acreage. London and Manchester salesmen speak highly of their quality, and report that Victors will keep their bloom and have a fresh appearance after being in the market some days, when other early Potatoes have become discoloured and unsaleable.

The stock we offer is the true yellow-fleshed variety and not the white variety, which is often substituted.

Price per cwt. and ton. State requirements to

W. W. JOHNSON & SON,
Seed Growers and Merchants, Boston, Lincolnshire.

BULBS, TO THE TRADE.

A SPLENDID LOT OF ANÆCTOCHILUS,

Quantities of **LÆLIA FLAVA**, **NEW ONCIDIUMS**, and many other

RARE and VALUABLE ORCHIDS.

THE

Gardeners' Chronicle.

SATURDAY, OCTOBER 1, 1892.

EDGE HALL.

THERE have been Dods of Edge ever since the time of Henry II., and judging from the name, even as far back as Saxon times. Anthony Dod was one of the glorious few with Henry V. at Agincourt, and was made Sir Anthony on the field. The present proprietor, so well known to your readers, has, metaphorically, changed the sword for the pruning-hook, and become equally eminent as a man of peace.

I am not going to attempt to describe Mr. Dod's garden—that would require a specialist in hardy flowers; and the few plants I am going to mention form but a very small fraction of what is rather rare, beautiful, or well cultivated. The house is a low rambling, Ivy-clad stone house, which looks very home-like, with the lovely, quaint, old-fashioned flower-garden embracing it lovingly on three sides. On the side where the drive comes up to the house, there is a lawn with raised rocky beds, where alpine and rock-loving plants are grown; it is very pretty to see some delicate little flower like the Androsace peeping out from between two rocks. One is also filled with wonder how Mr. Dod makes so many things to succeed in spite of soil and climate, both of which, so far north as he is, are often malicious enemies.

The garden proper is very cunningly devised to show its treasures gradually by reason of a wall and deviana paths and tracks. The great quality about it is what one might call the nook quality, and there is one corner where the garden presents the most glorious glow of colour, it would defy even the brush of Mr. Alfred Parsons to paint it, or the pen of Mr. Ruskin to describe it. Two plants must attract the attention of every flower-loving stranger whom Mr. Dod takes in. I am a raid there are too many of these. They are *Gypsophila paniculata* and *Geranium Wallchianum*. The secret of cultivating the first-mentioned beautiful plant is evidently understood here. One was as large as a fair-sized shrub, and was completely draped with its gauze-like diffuse panicles of snow-white flowers. The Nepanese Geranium was very rampant, and its delicate sky-blue blossoms were produced in lavish profusion.

There were many other species of Geranium in flower, including the prettily-veined *atriatum*, and nearly as many of *Campanula*. Other plants that caught one's attention were the Spanish *Sedum maximum*, *Rudbeckia rosea*, and the various *Lythrus*s and *Polygonum*s. In the rockwork *Ranondias* grow like weeds, and the *Cyclamens* brighten every shady corner. The Lenten Roses thrive, but not so the Christmas.

Another interesting feature of the garden at the present time is the autumn Crocuses and Colchicums. Tufts of these are flowering by the sides of the walks. *Colchicum Parkinsoni* and *C. speciosum* are very pretty species.

Herbaceous plants which flower in the autumn are generally speaking taller than the earlier sorts, they have had all the best growing weather in which to lay in a store of food for flower and fruit as well as foliage, and have not been interrupted in their upward growth by early formation of flowers. Standing at this time of the year in the old vegetable garden at Edge Hall, now full of flowering plants, it seems as if most of the plants were about 6 feet high. There is *Spiræa kamschatika*, 8 feet high, with clusters of pendulous, but not showy yellowish flowers; *Silphium laciniatum*, the Compass Plant, 5 feet high, flowers pale lemon-yellow, with large coarse leaves. The leaves of this plant are not only vertical when exposed to light, back and front of leaf being of the same structure, and presenting same deep green colour, but they place themselves in a vertical plane, which more or less coincides with the meridian of the locality whence they derive their name of Compass Plants of the Prairies. The vertical position is only assumed in a sunny spot; in the shade, they tend to become horizontal. The mode of reading these "compasses" is said to be a "perfectly easy thing when you are used to it."

Phloxes, *Helianthus*, and *Asters* are just now very showy. *Aster Thompsoni*, a plant about 3 feet high, and as much through, densely covered with pale lilac flowers. *Anthemis tinctoria*, growing by a hedge in a thick mass, is very bright. Growing in the shade of a Spruce, we saw some bright flowers of the hardy Cyclamen, they seem to flourish in the dead pine-needles; they have no competitors, for very few things can grow in such a situation.

Besides the *Michaelmas Daisy*, blue tints are furnished by *Eryngium*, *Echinops*, *Catananche creulea*, and *Gentiana acaclpiadea*, not bright certainly, but with a charm peculiarly their own.

Potentilla nepalensis is a pretty plant not often seen, flowers rich pink with darker centre. *Hypericum Kalmianum* is a distinct St. John's Wort, with abundant clusters of bright yellow flowers. *Hypericum reptans*, a creeping St. John's Wort, and *Sedum trifidum*, with pink leaves, both from the Himalayas, are now in flower. *Omphalodea Lucilæ*, a dwarf rare plant with pale metallic-blue flowers, and *Salvia hiana*, a sage with peculiar purple flowers, are both pretty plants. *Boltonia asteroides* is graceful, with Aster-like lilac flowers. The familiar *Anemone japonica alba* has here assumed a curious aspect, the leaves being curled like coarse Parsley; but these mis-shapen leaves are not accompanied by flowers. *Heliopsis scabra* is a rich yellow Composite. *Tunica saxifraga* forms a nice tuft of pink feather-flowers. Growing in a large pan is a mass of *Parnassia palustris*, very full of its interesting white flowers. All these together with many other interesting plants, seem to fill the available space, and make one wonder where the spring and summer blooming plants find room. In this garden, the plants' needs are considered first, the effect is only a secondary consideration.

NEW OR NOTEWORTHY PLANTS.

CALANTHE SANDERIANA, Rolfe, n. sp.*

This handsome *Calanthe* is a native of East Tropical Africa, whence it was introduced by Messrs. F. Sander & Co., of St. Albans, a short time ago. A plant was exhibited at a meeting of

* *Calanthe Sanderiana*, n. sp.—Terrestrial. Leaves tufted, petioles 6 to 8 inches long, blade elliptical-lanceolate, acuminate, 12 to 15 inches long, 4 to 5 inches broad. Scapes equaling or a little exceeding the leaves; racemes many-flowered. Bracts ovate-lanceolate, acuminate, 4 to 8 lines long. Sepals elliptical-lanceolate, acute, 10 to 12 lines long, 4 to 4½ lines broad. Petals obovate-lanceolate, acute, a little shorter and broader than the sepals, and, like them, pale lilac, shading off to lilac-purple at the margin. Lip as long as

the Royal Horticultural Society on August 9 last, and received an Award of Merit. It is allied to *C. natalensis*, Rehb. f., but has larger flowers, and a much deeper-coloured lip. The scape is a little taller than the leaves, and bears a raceme of numerous flowers. The sepals and petals are pale lilac, shading off to lilac-purple at the margin, and the lip rich deep purple, with some brown on the crest. The somewhat flattened spur is usually about 1½ inch long. Dried specimens were collected by Sir John Kirk, but the species does not appear to have been previously described, and the above name is therefore proposed for it, in honour of its introducer, Mr. Sander. It is a very attractive species, the dark purple lip forming an elegant contrast with the paler segments, and will doubtless prove as easy of cultivation as its allies. *R. A. Rolfe.*

CUSPARIA UNULATA, Hemsl., n. sp.*

This shrub, or small tree, is a native of Brazil, and belongs to a small group of the Rutaceæ peculiar to tropical America. They are mostly small trees, of Palm-like habit, with unbranched stems, a crown of handsome foliage, and axillary racemes of usually showy flowers. The petals are more or less completely combined, in some quite fused, forming a vase-like corolla, characteristic of a totally different natural order. *Erythrochiton braziliense* is a very striking member of this group. *Cusparia undulata* is a plant worth growing for its ornamental foliage, although one of the least showy of its congeners. It is not unlike an *Aralia*, having palmately compound leaves with five leathery leaflets; and the white flowers, about three-quarters of an inch long, are borne in racemes from the axils of the leaves, which overtop them.

The history of this plant is unknown, though there is no doubt it is from Brazil, where several closely-allied species are at home. It flowered at Kew in 1886, and again this year. I may add, that *Cusparia* is united with *Galipea* in Bentham and Hooker's *Genera Plantarum*, but the discovery of several additional species since the publication of the part of the work dealing with the Rutaceæ, afford evidence that the differences are sufficient for generic separation. *W. B. H.*

ORCHID NOTES AND GLEANINGS.

CATLEYA BRYMERIANA ×.

PRESUMED to be a hybrid between *C. superba* and *C. Eldorado*, found in the Rio Negro district of Brazil. It was described by Reichenbach in our columns of 1883, pt. ii., p. 492, and is now figured in *Lindenia*, t. 313.

CYTOPEDIUM PUNCTATUM.

The very curious and beautiful *C. Saintlegerianum* of Reichenbach is now considered to be identical with the above-named species, which was known

the sepals, three-lobed; side lobes falcate-linear, 3 lines long; front lobe obovate-bilobed, 9 lines broad; disc with three prominent verrucose keels, of which the central one is the longest; spur somewhat flattened, 1 to 1½ inch long; colour of lip rich purple, with the basal part of the crest brown, and the spur lilac. Column short and stout, white. Native of East Tropical Africa. *R. A. R.*

* *Cusparia undulata*, Hemsl., nova species.—*C. toziferæ* affinis differt foliis 5-foliolatis foliolis insigniter undulatis, floribus fasciculatis. Arbuscula simplicicaulis vel demum pauciramosa, apice tantum foliosa. Folia longe petiolata, digitatum 5-foliolata, cum petiolo usque ad 2 ped. longa; foliola distincte petiololata, subcoriacea, minute punctata, laevicollata, inæqualia (ejusdem folii 5—12 poll. longa), vix acuta, basi cuneata, marginata, subtus pallidiora, primum obscurissime strigillosa, demum glabrescentia, nitida, petiolulis validis basi incrassatis primum lanatis; petiolulus 8—12 poll. longus, teres. Flores albi, subbilabiati, fasciculato-racemosi, circiter 9 lineas longi, brevissima pedicellati, racemis pedunculatis quam folia brevioribus; sepala ovata, acuta, æquilinæam longa; petala linearicilobata, obtusissima, intus extusque pubescentia, conniventia vel conglutinata nec connata; stamina 3 superiora fertilia, filamentis extus ubique pilosis itatis juxta antheras longius pilosis vel barbatis basi glutinosis et cum petalis agglutinatis; ovarium pilosum, in disco cupulato fere omnino immersum, 5-loculare. Fructus igootus.

to Linnæus, and which flowered in the Glasgow Botanic Garden so long ago as 1835. It is widely distributed in tropical America. It is remarkable for the circumstance that the bracts of the panicled inflorescence are large and spotted like the segments of the flowers themselves. *Lindenia*, t. 344.

EPIDENDRUM WALLISII.

The racemes of this plant are terminal as well as lateral, the individual flowers fragrant, with golden yellow segments spotted with crimson, and a broad four-lobed white lip with radiating purple lines, and a yellow disc; native of New Granada; described by Reichenbach in these pages, 1875, pt. ii., p. 66, and now figured in *Lindenia*, t. 341.

CORYANTHES MACROCORYS.

A new species described by Mr. Rolfe, with Stanhopea-like flowers of a greenish-yellow spotted with reddish-brown. "The usual shape of the helmet in this strange genus is that of a rounded hollow pouch, rather broader than long. In the present species, this organ is elongated considerably longer than broad, placed close to and parallel with the ovary, and very fleshy." It is also quite destitute of hairs. The mesochil is much longer than usual, separating the helmet from the bucket by a distance of 1½-inch. It is figured in the *Lindenia*, t. 342.

THE CULTURE OF COCHINEAL IN TENERIFFE.

A VERY interesting account of cochineal cultivation in Teneriffe has recently appeared in a Foreign Office "Report on the Social and Economical Condition of the Canary Islands," from which we call the following:—The position of cochineal as a commercial product is stated to be next in importance to the Vine. The plant was originally brought to the Canaries in 1826, and met with great opposition from those who were afraid that this new and loathsome form of blight would spoil their Prickly Pears; in fact, in the previous century it was forbidden to land cochineal at all. Prejudice was overcome, and it was found that the Cactus, which grows freely in the islands, was best adapted to the insects' wants; also that the cheapness and the abundance of labour, and the climatic conditions, allowed it to be produced more plentifully and of better quality than in Mexico, Honduras, and Guatemala, the countries which had hitherto furnished the markets. As an indication of the progress cochineal made in the English market in the early part of the present century, it is stated that in 1814, 176,259 lb. were sold in London, at about £1 16s. per lb.; in 1820, 158,840 lb., at about £1 5s. 6d. per lb.; and in 1830, 297,985 lb. at about 10s. 6d. per lb. The first shipment from the Canaries was in 1831, and consisted of 8 lb., which in ten years had increased to 100,566 lb.; in 1850, to 782,670 lb.; in 1860, when cochineal was first chemically known, to 2,500,000 lb.; and in 1869, to the highest total of 6,076,869 lb., with a value of £789,993. The population at that period, it is said, was 270,000, so that cochineal alone produced a revenue of about £3 5s. to every man, woman, and child in the place. All the aniline dyes were discovered by this time, but were not commercially manufactured to such an extent as to seriously interfere with cochineal. The islanders, however, became somewhat alarmed at the price, and began to talk about over-production, and the means of preventing it. In 1874, the crisis had reached a more acute stage, and the price in the London market went down to an extremely low point, and the cochineal industry suffered a collapse.

The manufacture of aniline dyes received a sudden impulse in 1879, owing to the tropical rains, which gave rise to rumours of a short cochineal crop, and caused the price to jump from 2.45 pesetas to 3.62 pesetas, and even more. The damage was exaggerated, but the evil was done. The merchants, who congratulated themselves upon the ready sale of their old stock at enhanced prices, were astounded,

and in most cases ultimately ruined by the fall which ensued, the best qualities of dried cochineal going as low as 10*d.* and 11*d.* per lb. Some recovery has taken place now that it is known that cochineal is, after all, the only red dye which satisfactorily resists hard wear and heavy rain, but the output for 1890 was only valued at £60,940. Though the value of the exports have fallen from £845,390 in 1869, yet

was able to gain as much as two pesetas a day, and his wife and children to find constant employment at equally remunerative rates. The merchant and shipper benefited, and the expenditure of all classes rose by leaps and bounds. Land was unpurchasable, and everyone wanted to buy. Crowds of dealers were only too glad to buy the cochineal, and to employ their capital or credit by storing it. The

The English have been reproached as being the only gainers by cochineal in the end. How this can be is not apparent. It is true that the dye was chiefly sold in London, but such is no longer the case. On the other hand, some of the furniture and saddlery still exists, though a little out of repair; the fields which were largely constructed on English capital have not vanished, and after all, it was not the fault of Great Britain, if extravagance and waste left nothing but a memory of better things, instead of a number of fat kine to tide over the somewhat dismal period to follow. Below a certain altitude Cactus was planted in every corner, so that grain and most necessaries were constantly imported, and the bewildered farmer found he must either root the Cactus up or starve. The cochineal growing as it did near the coast, caused a great area to be brought under cultivation which was formerly worthless; for instance, the slopes above Santa Cruz, in Teneriffe. The land so reclaimed, however, was not paid for when the collapse came, and left a load of debt, which greatly impeded development for years to come.

The land which owes its existence to cochineal is now largely planted with Tomatoes, &c., and if ever it rises to the value of its original cost, it will be because of the fruit and vegetable trade, started and fostered by Englishmen, and maintained entirely by the English demand.

PTYCHORAPHIS AUGUSTA.

This is an elegant little stove Palm, which has been introduced to Kew this year from the Nicobar Islands. It is as graceful as *Coccoloba Weddelliana* or *Geonoma gracilis*, and it grows as freely under cultivation as either of these popular Palms. Nurserymen and others interested in Palms would, I believe, find it worth while to introduce this *Ptychoraphis* in quantity, and the following information may serve to put them on the scent.

Kurz, writing in the *Journal of Botany* in 1875, of some plants of the Nicobar Islands, says of this Palm:—"One of the most conspicuous features of the Nicobarese vegetation is *Areca Augusta*. It pushes its head above the highest forest trees, and forms, so to say, a Palm forest above the true forest, rendering thus the aspect of the landscape more Brazilian than Indian. It is frequent all over the so-called northern group, while it becomes scarce in the southern group." He also states that it seeds abundantly, each tree yielding about a mannd of fruits yearly. It forms a slender tree 80 to 100 feet high, the smooth annulated trunk only a foot in diameter. The leaves ultimately become 8 to 12 feet long; the pinnae, 2 to 3 feet, narrow-linear, acuminate, bright green. The fruits and seeds, of which figures are given in the accompanying picture, are elliptical oblong, red when ripe, a groove, similar to that of the Date-stone running along one side of the seed, the albumen of which is ruminated as in a Nutmeg. A quantity of the seeds have recently been distributed from Kew.

The genus *Ptychoraphis* was created by Beccari, and comprises only three species, all Malayan. It is allied to *Ptychosperma* and *Pinanga*.

A second species of *Ptychoraphis*, viz., *P. singaporensis*, also called *Ptychosperma*, is also in cultivation at Kew, and the third one is the plant which has lately been distributed as *Rhopaloblaste hexandra*.

Palms appear to have been exceptionally unfortunate in regard to nomenclature. Horticulturists will, no doubt, regret that Kurz's simple name for the plant here figured, viz., *Areca Augusta*, proved a wrong shot. What are termed "crack-jaw" names by the laity are abundant among Palm names. The unoffending little brother of the plant here figured has been well (or ill) treated in this respect by the botanists. One called it *Ptychosperma singaporensis*; another followed with *Rhopaloblaste*, and now we are to call it *Ptychoraphis*. Would plant sponsors be offended if cultivators appealed to them for simpler names? The new generic names are much more "crack-jaw," as a rule, than the old. *W. W.*

FIG. 63.—PTYCHORAPHIS AUGUSTA.

cochineal still remains one of the principal articles of export, because it is easy to cultivate, and because the Cactus grows in situations unsuitable for other plants. The economical results of the cochineal culture are yet widely felt in the islands.

Immediately after the collapse of the wine trade, the owners of land found themselves face to face with an unsuspected mine of wealth, which enriched them almost without an effort on their own part. Every one shared in the golden shower. The peasant

landed gentry ordered expensive furniture, silver-mounted saddlery, and other costly goods from Europe, or spent their time in general dissipation.

Retribution was sudden, swift, and universal. Aniline dyes took the public taste, and left merchants loaded with stock which never ceased to fall. Money-lenders with heavy mortgages on comparatively worthless property, resident landowners insolvent, and a peasant population temporarily demoralised by high wages and easy living.

ENGLISH GARDENS.

MR. F. L. OLMSTED, the distinguished American landscape gardener, has been staying in England during the summer. The following extracts from a letter to the *Garden*, will, no doubt, interest our readers:—

"I enjoyed the park at Chatsworth, did not like the terrace, but found, notwithstanding some bad anomalies, the results of Paxton's work in the pleasure grounds more agreeably interesting than I had in some way been led to suppose, or than I remembered them. I suppose this is the result of growth. Justice can often not be done to a landscape gardener's design in less than fifty years after the work has been initiated. Nor then or ever, unless it has been in the hands of one in sympathy with nature.

"Reviewing all that I have seen in England, it appears to me that the selection and disposition of trees and plants, the modelling of surfaces and the arrangement of roads and walks and architectural conveniences, with a view to pleasing general effects of scenery, have been of late much confused and often lost sight of in efforts to provide brilliant local spectacles, to display rarities, curiosities and luxuries of vegetation, and to exhibit master-pieces of horticultural craft and costly garden *bric-à-brac*. Vast numbers of trees have been planted without knowledge or soundly-formed anticipations of what they will become. Many of them are failing, and many that are not failing are conspicuously offensive, because of their unfitness to combine with the native elements of English scenery. Since my earlier visits the country has lost something of picturesque interest, mainly I think through agricultural and economical improvements; but a little, I am inclined to think, because of some slight and probably temporary turn of public sentiment toward prosaic neatness and formality.

"Since my last visit there has been a decided abatement of the bedding-out nuisance, and of all the garish and childish fashions that came in with it. The gardeners and others with whom I have talked have been generally conceding—some with evident regret—that it was going out of fashion. Any who think that with it their occupation will be gone had better come quickly to America, where all the beauty that I have been aiming to provide on various grounds is wholly put out of countenance by it. There has never been a square yard of bedding out on any ground under my direction."

CLEISTOGAMY.*

In the admirable *Forms of Flowers*, by Charles Darwin, the term *Cleistogamic*, proposed by Kuhn ten years before, in 1867, for a certain class of fertile flowers, is adopted. "They are remarkable for their small size, and from never opening, so that they resemble buds; their petals are rudimentary, or quite aborted; their stamens are often reduced in number, with the anthers of very small size, containing few pollen-grains, which have remarkably thin transparent coats, and generally emit their tubes whilst still enclosed within the anther-cells; and, lastly, the pistil is much reduced in size, with the stigma in some cases hardly at all developed."

In regard to this, Mr. Darwin well says: "It is by no means easy to decide in all cases whether flowers ought to be ranked as cleistogamic. For instance, Mr. Bentham informs me that in the South of France some of the flowers on the *Vine* do not fully open, and yet set fruit; and I hear from two experienced gardeners that this is the case with the *Vine* in our hot-houses; but as the flowers do not appear to be completely closed, it would be imprudent to consider them as cleistogamic." Commenting on what has preceded, he adds,— "The flowers

of some plants which are produced very early or very late in the season do not properly expand; and these might, perhaps, be considered as incipiently cleistogamic." A cleistogamic flower is to be considered in its broadest sense as one which is capable of self-fertilisation, but never fairly opens. In a restricted sense, it might be considered only as one which not only does not open, but which has had some of its floral parts modified or aborted.

When Mr. Darwin wrote, some fifteen years ago, little attention had been given to this class of flowers. Cleistogamy had been noted in but fifty-five genera, and the treatment of the subject by this acute observer and profound reasoner, is very much as if all the facts that could be gathered had been collected, and were before him. For instance, stress is laid on the fact that a considerable proportion of the genera noted as cleistogamous have irregular flowers; but since Mr. Darwin's time, the list of genera in which cleistogamy has been observed has been considerably extended. I have myself placed on record instances in *Jasminaceæ*, *Hydrophyllaceæ*, *Caryophyllaceæ*, with other genera, in regular flowered orders, which have been already noted, and now add a notable instance in another regular-flowered order—*Rosaceæ*—*Dalibarda repens*. In the latter part of July, confined to the sea-side inn at Seal Harbour, Maine, by temporary illness, botanical friends, and especially Mr. John H. Redfield, Conservator of the Academy of Natural Sciences of Philadelphia, brought me daily portions of their collections; *Dalibarda repens* was among them. There was a profusion of its pure white flowers, on scapes several inches long. I was surprised to find them purely staminate. Supposing the plant monoecious, search for the pistillate was made, and the fruiting calyces on very short pedicels around the root-stocks supposed to be them. Further examination showed minute buds, and others in various stages of fruitfulness down to the mature fruit. The buds proved to be perfect in their sexual organs, the stamens, however, being reduced from the indefinite number in the male flower to five—the uniform number in all the buds. These details are mentioned because heretofore my observations have been made on a large number of individuals in their place of growth. In this case, Mr. Redfield returned to the locality, and confirmed my observations. It may be well to note here, that although this appears to be the first instance of cleistogamy recorded in *Rosaceæ*, sexual irregularity has been observed in the dioecious *Rubus chamæmoris*, and purely pistillate forms in *Fragaria virginiana*.

I desire particularly to refer to observations made by me during the past three or four years, and published in the *Proceedings of the Academy of Natural Sciences of Philadelphia*, in regard to the flowering conditions of many species of *Polygonum*. In the most limited sense, cleistogamy exists in *Polygonum* acre. In many cases, the secret flowers can be found under the ochrea in the lowest node, the only external evidence of their existence often being a gland-like swelling as the seeds mature. But in a general sense, every seed that matures in most of the species of *Polygonum* I have had an opportunity of examining in a living state, is the product of a flower that never opens, and has its pistil fertilised by its own stamen very early in the bud. Every flower so fertilised is fertile. But besides these absolutely fertile closed flowers, there are numerous others, which expand, and seemingly have the stamens and pistils perfect—have honeyed secretions freely availed of by bees and other insects, which I have never found produce a seed.

There are also other facts in connection with cleistogamy worth noting. I have seen *Nemophila insignis* very frequently under cultivation for nearly half a century, but with no indication of cleistogamy; but in some of its wild habitats in California I have seen immense quantities flowering all the summer as our *Violets* do, in a purely cleistogamic condition—so abundantly seeding that there seemed more fruit

than foliage, and the wonder was, how the plant supported all.

Numerous flowers (and in this I would include most of the *Compositæ*—a tenth of the whole vegetable kingdom), as I have shown in various papers, fertilise in the bud before the corollas open, and, so far as results are concerned, might be classed as cleistogamic. But for the purposes of this paper, only those strictly in accordance with the definition are employed.

With these before us, we will now ask what is the significance of cleistogamy? Mr. Darwin's only conclusion is given in these words:—"Cleistogamic flowers afford, as just stated, an abundant supply of seeds with little expenditure; and we can hardly doubt that they have had their structure modified and degraded for this special purpose, perfect flowers being still almost always produced, so as to allow of occasional cross-fertilisation."

Do the facts warrant this inference? There is a vastly greater "expenditure" in plants which self-fertilise than in those dependent on insect aid. Nearly all our common weeds are self-fertilisers, and—take the common Chickweed as an illustration—every flower produces seeds. Plants which are dependent on insect aid—take many *Orchids* for this example—have comparatively few flower seeds, because insects so often fail to do the work. In plants undoubtedly dependent on insect fertilisation, the majority never seed; in self-fertilisers, all—or, we may safely say, nearly all. There is a great expenditure of effort, not a less. The trifling gain in the production of pollen is immeasurably counterbalanced in the immense production of seed. In purely cleistogamic flowers, as illustrated in *Nemophila*, this contrast is still more striking.

It is surprising that so acute a logician as Mr. Darwin did not himself see the fallacy of his own reasoning. He shows that in many instances, especially *Violets*, the perfect flowers rarely produce seeds, the whole function of seed-bearing being left to the cleistogamous class—a fact which those familiar with American *Violets* can fully endorse. Surely the production of millions of seedless flowers must be a waste of expenditure, for which no amount of cleistogamic seed production can compensate.

What, then, is the significance of cleistogamy? Absolutely none from any standpoint connected with the welfare of the race. In the life of plants there are two forces interdependent and yet antagonistic—the vegetative and the reproductive. There can be no reproduction till the vegetative force has in some measure received a check. The reproductive energy is then proportionate to the check vital force receives. The practical horticulturist understands so well that when a plant or tree is growing with great vigour, it will not flower—or, if it flower, seed-production is a failure—that it would be a waste of time to bring in illustrations here. All floral parts are but the organs of vegetation transformed, and are formed only after the nutritive forces which give such energy to vegetative growth have been considerably checked. Waves of vegetative strength, however, often flow into the inflorescence. Parts which under ordinary pressure would be sepals, petals, or stamens, will still continue in a measure leaves, or not perfectly transformed from leaves to the destined organs. Barrenness then ensues, and this barren influence, the result of undue vegetative energy, will often permeate a whole flower. On the other hand, the reproductive energy is powerful just in proportion to the subjection of the vegetative force. To use the language of Mr. Darwin, "we may confidently believe" that a cleistogamic flower is one in which the vegetative force has become so much more than usually subservient to the reproductive, that it has not been able to produce petals or the usual series of stamens; and that this condition, being favourable to reproduction, has resulted in the very fruitful cleistogamic class. The fruitful cleistogamic condition is but an exemplification of a common saying, but an undeniable proposition, that Nature makes an effort for preservation of life proportionately to the chances of destruction.

* "On the Significance of Cleistogamy," by Thomas Meehan, State Botanist of Pennsylvania; Vice-President, Academy of Natural Sciences of Philadelphia; a paper read at the Rochester meeting of the American Association for the Advancement of Science, and communicated by the Author.

NEW ALPINE PLANTS.

M. LE CHEVALIER SOMMIER, of Florence, who has botanised and travelled, chiefly in mountainous and cold countries of the northern hemisphere, has kindly given to our alpine garden a number of alpine and mountain plants which are of considerable decorative value, and not yet familiar in cultivation. From the cold districts of Russian Lapland he has brought us seeds of the two following species, which are worthy of a detailed description. *Primula Finmarchica*, Jarg. (*P. norwegica*, Retz.), an elegant and graceful form of *P. sibirica*, Jarg.; not the sibirica of gardens, which is only the common *P. farinosa*, but the true sibirica, that is to say a *Primula* not unlike *P. involucrata*. *P. Finmarchica* differs from the Siberian species by having smaller flowers, borne on shorter, erect stems, and by the length of the corolla-tube which scarcely extends beyond the calyx. From a horticulturist's point of view the blossom is quite different to that of sibirica, owing to the dark lilac colour of the corolla and its clusters of smaller, less abundant and more crowded blossoms. It flowers once in summer and again later on in autumn. It is cultivated as are the Himalayan species in light, porous earth and in full sunshine; it is increased by division and seed.

Polemonium campanulatum is a dwarf close plant of delicate habit, with pendent flowers like well-opened bells, lilacy-blue and with golden-yellow stamens. It blooms in April and May, and likes the coolness of partial shade. The plant does not flower freely in the Geneva climate, but does admirably in our botanic garden of the Linnæa. In the summer of 1890, M. Sommier, accompanied by Dr. Levier, of Florence, made a botanical excursion in the Caucasus, and sent us thence 160 packets of various seeds, among which were found a certain number of undescribed species. Many of these plants have already flowered with us, and are valued acquisitions for the rockery and alpine garden. The following are those which most attracted me:—*Androsace albana*, Stev., from the alpine regions of central and eastern Caucasus, at an elevation of from 8000 to 10,000 feet. The plant is biennial or perennial, the foliage is in pretty little rosettes, the edges daintily toothed, bright green, the flowers very shortly stalked, growing in dense compact umbels, the corollas pinkish-white. It blooms from April to July, requires sunshine, a light soil, and is easily reproduced from seed.

Androsace caucasica, Sommier and Levier.—A pretty new species found by these explorers on the Elbruz, at an elevation of between 10,000 and 11,000 feet, among stony and sterile rubbish. It is apparently biennial, but here, in the garden, it remained after flowering, and seems as if it would bloom again next year. It is a dwarf plant, forming on the ground a cluster of beautiful clear pink flowers, almost stemless, closely packed one against another, and recalling our *Androsace glacialis* of the Alps by the abundance of densely-arranged blooms and their bright pink colour. But it is really quite another plant, and resembles far more closely *Androsace nana*, of Sicily. The leaves are narrow, the edges toothed, arranged in a rosette, from the centre of which the flowers spring. It blooms here all the summer, and, in fact, is now still in bloom in the Linnæa.

Cerastium purpurascens, from the alpine regions of the Caucasus, is the best species of the genus, and quite different from other species grown in our gardens. I nowhere find this plant mentioned as "in cultivation," and I believe that, thanks to M. Sommier, our garden is its introducer. It is a curious, not stoloniferous species, with a thick, almost bulbous root, with a central thick rhizome, into which the plant entirely retires after fructification. This central stock bears floriferous branches from $2\frac{1}{2}$ to $3\frac{1}{4}$ inches long, with oblong linear-lanceolate leaves, and on the summit an umbel of large, or indeed very large, flowers of a beautiful blue colour, which contrast well with the purplish hue of the sepals. When the plant is in bloom it is most effective, and forms

a splendid ornament for the rockery. It is a new plant, and very valuable, which I cannot sufficiently warmly recommend for introduction into gardens. It can only be increased by seed, as the stock gives forth neither stolons nor side-shoots.

Coronilla cappadocica, Willd., from the mountainous regions of the Caucasus and Taurus, at a height of between 4500 to 7000 feet. A pretty herbaceous species, with stems trailing on the ground, the leaves glaucous, the flowers bright golden-yellow, borne on a pendent stem throughout the summer. It requires full sunshine, and is increased from seed. This is an excellent species for rockeries in full sun, and has the great advantage that during the warm summer months it bears an abundance of flowers, which contrast charmingly with the very bright colour of the foliage. *H. Correvon, Directeur du Jardin Alpin d'Acclimatation, Geneva.*

ABIES VEITCHII.

WE are glad to have the opportunity of publishing an illustration of the first cone of this species that has, so far as we know, been produced in Britain.

FIG. 64.—ABIES VEITCHII: BRITISH-GROWN CONE.

It was obligingly forwarded to us by Mr. Croucher, of the gardens, Ochtertyre, Crieff. The cones that we figured some years ago, were native specimens, and in them the bracts were shorter than the scales, and in consequence concealed. But even in the Japanese specimens brought home by Mr. Maries, and in those figured by Dr. Mayr in his recent work on the *Abietineæ of Japan*, there is considerable variation in the relative length of bracts and scales. In the specimen from Col. Murray's garden, now published, the cone is of a rich olive-brown colour, and the acuminate bracts not only project, but are bent downwards, and are of a lighter colour than the scales.

Mr. Croucher notes in his letter the peculiar growth of the tree, which is very slender in outline, with the lateral branches relatively short and somewhat irregularly disposed, so that between the regular tiers of longer branches, several much shorter branches occur at irregular intervals; and this mode of growth characterises the specimen in our own garden—indeed, all we have seen. Various other Firs have received, by misadventure, the name *Veitchii*; but the one now referred to is the only one properly entitled to the name. The confusion was rectified in our article at p. 275 of our volume

Feb. 28, 1880, and in the *Journal of the Linnæan Society*, vol. xviii., tab. 20, to which we have nothing further to add as to the history of the tree.

A TRAVELLER'S NOTES.

(Continued from p. 350.)

THE BOTANICAL GARDEN OF CALCUTTA—an hour out of the town at the village of Seebpore—is a wonderful place. It is 272 acres in extent, possesses numerous fine avenues, the most noticeable being one of *Grevillea robusta*, two of *Oreodoxa regia*, their stems rising straight and tall, like great gun-barrels; another along the river-bank, three-quarters of a mile in length, of *Terminalia Catappa*, 60 to 70 feet high, with great ovate red-tinted foliage as large as a *Magnolia*, a splendid grove of Bamboos in great variety, a clump of *Brownea*s, triangular in shape, 50 feet at the broadest end, and 200 feet long; an avenue of the same genus over 100 yards long, forming a perfect tunnel; Palms such as I have never seen, fine trees of Mahogany, a noble avenue of *Casuarinas*, a grass-covered house, octagonal in shape, each side of which octagon is 30 yards long, one of the finest I have seen in or out of Europe; a Banyan, 106 years old, the main stem of which is 16 feet in diameter (see page 409); a splendid avenue of the Toddy Palm, miles of roads, numerous ponds winding in and out in every direction, on which the *Victoria regia* lives in cold weather, and turtles sit and eat its leaves; and a frontage 1 mile in length along the bank of one of the world's finest water-courses, the great Hoogli river. It, as a garden, is like the Taj as a building, hear what you may, or picture to yourself what you will, when you see both you will yet be surprised.

The luxuriance of the vegetation tells a tale of what the hot season must be like; in England we cultivate to grow, but at Seebpore the difficulty is to keep within bounds. Mr. Proulock, an old Kew man, accompanied me round the garden.

The shape of the Botanic Gardens is peculiar. Standing on the bridge, the view is very pretty. In the tank were some *Victoria regia*—one just bursting a flower. A few live through the cold season, but not all, and turtle are very destructive to their leaves. For three-quarters of a mile along the river bank runs the magnificent *Terminalia Catappa* avenue—a most fine sight; the stems are tall and straight, the heads pyramidal, and the large handsome foliage prettily tinted with red; most of the specimens are from 60 to 70 feet high.

Turning from the pond, and looking at the river still from the same bridge, one is struck by the great breadth of this stream; in the rains it often rises 12 feet; its force at that time must be irresistible. A little to the left of the road, along the river bank, towards the east, is a great grove of Bamboos, opposite a clump of *Pinus longifolia*. Some of these Bamboos are very fine, and very many species are here represented. Those I chiefly noticed were *Dendrocalamus obovatus*, 35 feet high and some 12 feet through—so thick as to be perfectly impregnable, like a bundle of lead pencils; *Melocanna bambusoides*, of straggling habit, but producing still strong canes, used for pig-sticking; the big-caned *Gigantochloa macrostachya*; a fine specimen of *Bambusa nutans*, somewhat straggling in habit; a quite yellow-stemmed variety of *Bambusa vulgaris*; a very pretty clump of *Bambusa nana*, with thin stems and overhanging foliage—remarkably graceful; and a very peculiar species, *Dinochloa Macleanardii*, with twisted curled stems, some 20 feet high.

Dendrocalamus giganteus is represented [figured at p. 335 of this volume] by a fine specimen, but not so large as those in Ceylon—a very fine piece at Seebpore is 70 feet high, but at Peradenya I think the clumps are bigger in circumference. I measured some bracts fallen off, they were exactly 2 feet across; a peculiarity is noticeable on the young stems—for almost their entire length they are covered with a whitish, thick, wax excretion; in the older canes this is absent.

At the north end of this clump of Bamboos, one looks down one of the avenues of *Oreodoxa regia*, with a white stone vase at the end, from which the other avenue of the same Palm runs down to the river bank. These two avenues are wonderfully fine; their regularity, evenness of stems, &c., would lead one almost to think they were the work of man and not of Nature. Near the end of the *Oreodoxa* avenue first referred to is a young avenue not long planted, though the specimens are already of considerable size, of *Swietenia Mahagoni macrophylla*, a large-leaved variety of Mahogany, which originated

in this wise: some seed was got out from Kew of what was supposed to be the typical Mahogany; but a very short time after germination, Dr. King noticed they were different from the type, having larger foliage, hence the name *macrophylla*, which he gave it. Adjoining this is an avenue of the Rain Tree.

If one continues along the river bank after having been through the clump of Bamboos, and passing in returning a fine piece of *Dendrocalamus Hamiltonianus*, so common in the valley of Sikkim, and one of *Bambusa siamensis*, exceptionally graceful and pretty, one still passes beneath the great *Terminalia* avenue. On the river bank, Mr. Proudlock pointed out to me the remains of a stem of *Corypha elata*, the principal portion of which had been shipped to Kew on New Year's Day. The stump of this Palm was exactly 2½ feet in diameter, and the peculiarity lies in its great spiral stem—sometimes the twist is in one direction, sometimes in another; why some specimens twist to the right and others to the left is unknown. When the one referred to arrives at Kew, they will have both instances of this peculiarity. A little further on, the bank is being raised—in some places as much as 5 feet; this is partly done to keep the Hougli within bounds in the rainy season, and partly to improve this portion of the garden.

I may here mention, much has been done all over the garden in raising the ground in certain parts, and causing it to undulate. The whole place, Dr. King tells me, was perfectly flat, much artificially must indeed have been done to make it the pretty spot it now is. The roads are very solid, made of broken bricks, with a fine sand on the top; they are perfectly level, that is to say, do not slope away on either side, on account of the heavy wash in the rains; for the same reason, the grass, which in places is very good, is 2 inches below the level of the roads.

Before reaching the great clump of Brownias, I have already mentioned, on which were a few isolated heads of bloom (for it is yet too early for these magnificent plants to be in full bloom), a fine clump of *Calamus* some 20 feet through is passed.

The Mahogany avenue touches the Brownea group at this point, on the left of which is a pond with undulating banks, on one of which, amongst the luxuriant vegetation is a tall *Poinciana regia*, some 40 feet high, its large graceful foliage reaching to the water's edge; it is covered with the thick long brown pods peculiar to these plants. Masses of Palms on the other banks rise in the distance.

The eastern boundary is now reached, with the Howrah Gate, the principal entrance at one end. This entrance is reached from Calcutta, through the dirty native village of Seehpore, so a road is being constructed along the river bank to obviate passing through this village. Before reaching the Howrah Gate, another pretty view of the same lake is obtained with the Island in the centre; a group of Bamboos, with dwarf *Pandanus* beneath, and some great *Sissoo* trees (*Dalbergia Sissoo*) a most English-like looking tree beyond. On the right of the road leading to the Howrah Gate, is a row of *Jonesia Asoca*. I am told its pea-shaped flowers are very handsome, reddish in colour; and near by are some specimens of *Blighia sapida*, an African fruit known as the Akee, said to be very good; as well as four nice trees of *Adansonia digitata*, the Baobab, a deciduous tree, with big Malvaceous flowers. A great hush, spreading 20 yards through, of *Ficus Roxburghii*, is very striking, with its great leaves usually 1 foot long by 10 inches broad. Near the gate some more alterations in the ground-level are being made. I was much struck with the type of people employed, so different to the cringing, lazy, Bengalee. Mr. Proudlock informed me they were Daghars from some 150 miles up country, and spoke in very high terms of their working capabilities and general character. They receive from—at the present rate of the rupee—5s. 8d. to 8s. 6d. per month. Standing at the Howrah Gate, one notices three main roads leading into the gardens; one skirts along the north side, shaded by a fine avenue of *Borassus flabelliformis*, the Toddy Palm; one along the east running into the *Terminalia* avenue on the river bank, and one towards the centre of this part of the gardens. The one on the east side is the one I came along from the river bank, and it will be most interesting to follow the one which winds gently through grass, on which are fine single specimens, clumps, &c., towards the centre of the grounds, and towards the celebrated Palmetum.

Near the gate is a large Peepul Tree (*Ficus religiosa*), over which, on the great stem and branches are many creepers, chiefly *Philodendrons*, a fine

Tectona grandis, and a tall *Grevillea robusta*, with its rich dark foliage; it is strange to me how this plant lives, and grows on the hills in Ceylon, at several thousand feet elevation in the Nilgiris, as well as in the reeking oven-like temperature of the hot season of Calcutta. On the left, and not far down the road winding towards the centre of the garden, is a fine clump of Palms—great *Licalas*, handsome *Phoenix*, and a tall *Caryota urens*; whilst on either side are some tall, even specimens of *Araucaria Cunninghamii*. A big bush of *Bougainvillea glabra*, the shy-flowering form, is here in bloom.

A fine avenue of *Casuarina equisetifolia* lines a portion of the road—great trees, dwarfing all beneath; near to which are two fine specimens of *Eucalyptus resinifera*. Over one of the *Casuarinas* is a *Ficus repens*, many of its leaves being just 4 inches long. Tall, graceful pieces of *Cupressus torulosa* are on the left of the road, with some fine pyramidal specimens, 15 feet high, of *Juniperus virginiana*; on the right rises a tall *Araucaria Cookii*, and a fine group of *Livistona mauritiana*.

A moderate-sized *Bignonia*, from Columbia, called *magnifica*, was in flower; it has a pink tint. It is close to a fine *Bauhinia diphylla*—not remarkable, I am told, on account of its flower, but possessing very pretty foliage; so light and graceful is it, that in the distance it is not unlike *Adiantum Farleyense*.

On the right of this road is another lake, with pretty banks, sloping to the water's edge, winding in and out. A great *Albizia procera*, not less than 100 feet high, with foliage to the water's edge, overhangs it at one point. Beneath it, on one side, is an *Amherstia nobilis*; whilst a fine specimen of a *Pterocarpus*, from Java, is close by.

Still following the same road, and passing on the left a fine clump of *Araucarias*—the specimens ranging from 30 to 35 feet high, chiefly composed of *A. Bidwillii*, *Cunninghamii*, and *Cookii*—as well as a dwarf shrub, *Quassia amara*, from which our *Quassia* chips are derived, and which has a very curious pinnate foliage with winged petioles—the avenue of *Casuarina* referred to is reached. Over one of these creeps *Porana paniculata*, the Bridal Creeper, with long inflorescences of white flowers.

Beyond this short avenue, Mr. Proudlock pointed me out a shrub, *Strophanthus dichotomus*, with shoots several yards long, turning and twisting over the grass on all sides. He tells me it is a most gorgeous, brilliant red, five-petalled flower, with thin, wavy, thread-like petals, 6 to 7 inches long. Close by is a *Nutmeg*, which has to be protected during the hot season, and two groves of Palms. Here the road again divides into three, and the Palmetum proper is reached. At this portion of the grounds the garden is only a few hundred yards wide. At the commencement of the Palmetum, the *Borassus* avenue, named as lining the road on the north side from the Howrah Gate, is clearly seen.

The roads are beautifully smooth, carefully rolled, the motive-power being small, plump little bullocks in splendid condition, and wonderfully pretty creatures, so different from those one sees in the villages—some with great open sores, and many with tails twisted out of shape. The average Hindoo practises great cruelty on the animal, which from religious belief he dare not kill.

At the commencement of the Palmetum, near a small pond on the left, is a fine *Livistona* group, in the centre of which is the best specimen of the Egyptian Doom Palm, *Hyphæne thebaica*, I have yet seen. It is most distinctly branched, and is not far short of 30 feet high. From the base rise three shoots, two of which are three times dichotomously branched, the branches being several feet long.

Masses of Palms are dotted about. *Phoenix*, *Livistonas*, *Oreodoxas*, and on one side is a most effective mass of *Latania glaucophylla*, with broad grey foliage, stiff, upright, grey stems—a most distinct feature in this part of the garden. In a thick bed of *Rhapis*—much like, in fact Mr. Proudlock thinks it is, *humilis*, so thick as to be impregnable, just like standing in front of a Yew hedge—is a tall graceful specimen of *Caryota urens*.

Continuing toward the centre of the garden, a short avenue of tall *Oreodoxa* (not one of those already referred to) is reached, on the right of which is a large winding lake, and in the centre is an island, every inch covered with a small forest of Palms, great *Caryotas*, tall *Elais guineensis*, and the tall stiff foliage of *Arenga saccharifera* rise many yards. The growth is wonderfully luxuriant, and, being left principally to Nature, the effect is most impressive. The Palm-house at Kew is but a toy after all. Near here, on the left of the road, creeping

masses of various *Pandanus* cover many, many square yards, and some fine *Arengas* and *Oreodoxas* are behind a pretty circular avenue of *Polyalthia longifolia*.

There are some fine single specimens of Palms, most noticeable being *Corypha Gebanga*, with large broad palmate leaves; and *Corypha elata*, with a stem 3 to 4 feet through, with great, stiff spiny petioles, and broad palmate leaves several yards through. The specimen in question is not very high (as Palms go at Seehpore), but is an immense thing.

A group of hybrid *Phoenix* is very pretty, and *Phoenix rupicola* does well here, but does not grow much above 8 to 10 feet. *Ravenalia madagascariensis*—the first I have seen since leaving Ceylon—is fine. There are two fine pieces near the Palmetum. At the end of the Palmetum is a bridge over the largest lake, somewhat narrowed at this point. From here one looks straight to the Hougli river, and to the bridge from which I started.

Standing for a few minutes on this bridge I noticed some fine *Elais guineensis*, *Phoenix rupicola*, a pretty variety of *Areca madagascariensis*, a large *Dendrocalamus giganteus*, an *Attalea cohnn*, with tall stiff *Phoenix*-like leaves some 20 feet long, a great bush covering many yards of *Sanchezia*, green from the luxuriance of its growth; tall *Cocos flexuosa*, and some *Pomœa vitifolia*. This concluded my walk in the smaller and most interesting portion of the garden. *James H. Veitch*,

(To be continued.)

FRUIT CULTURE AT GLEWSTONE COURT.

DURING late years, the cultivation of hardy fruit has received increased attention, while its extension from a profitable point of view has been both recommended and discouraged by practitioners and theorists alike, and members of each class have arrived at such diverse conclusions, that would-be planters may well be in a dilemma and state of hesitation about entering upon this enterprise. In touching upon this subject, I do not pretend to be able to improve these matters. There are so many pros and cons—vital questions to be considered in connection with fruit culture for profit—that it is as advisable to be cautious in recommending its adoption as in condemning it. That a good profit may be realised by it I am, however, convinced, but to accomplish this, favourable conditions must be linked together, and for this reason it cannot become to any extent of general benefit to ordinary tenant-farmers, as some enthusiasts imagine it might. This, I think, is beside the question; capital, skill, suitable soil, favourable situation, security of tenure, &c., are indispensable to insure thorough success, and even when these are concentrated, the elements may blight bright prospects.

Nowhere have I seen the above necessary factors to success so happily united as at Glewstone Court, Herefordshire. Here, upon a favourably-placed fruit plantation of 12 acres in extent, the effects of Mr. Lee Campbell's capital, combined with his gardener's (Mr. Wright) intelligence and skill, are to be conspicuously seen; and although I cannot conjecture what the actual profits may be, there can be no doubt about there being a fair surplus after expenses, which must be considerable, are paid.

The situation is an open one upon the banks of the Wye, and is sufficiently elevated to escape very destructive frosts; while the soil is a light sandy loam, somewhat shallow, and having a natural drainage of red sandstone—conditions conducive to the formation of fruit-buds rather than of sappy wood. The fruits cultivated are Apples, Plums, Pears, Raspberries, and Black Currants. The former occupy the largest space, and are most profitable; Plums following next in both respects, and only 3 acres are devoted to Raspberries and Currants. The trees of Apples, Pears, and Plums are pyramidal and bush in form, are planted 9 feet asunder, and are 7 feet in height; and this kind of tree answers admirably upon soils of the above description, as their growth is moderate, requiring little pruning, and they are abundantly fruitful when quite young. Moreover, their dressing, pruning, and fruit-picking can be cheaply done, an advantage over large trees worth

consideration. As an instance of early fruitfulness, I may mention that a plot of Apples (Lane's Prince Albert), which when planted were two years' grafted, and cost 2s. each, bore fruit after being two years planted which realised the sum of 3s. 6d. each. All the trees are models of good cultivation, and exhibit Mr. Wright's skill in a marked manner; they are clean, healthy, and, when I saw them, those not relieved of their burdens were carrying heavy crops of fine clean fruit, many having their branches supported to prevent breakage from the weight. I do not remember the age of the oldest trees, but they are probably nine years planted, and the youngest are—600 Apples, Ecklinville Seedling—three years planted.

For market purposes, a few reliable varieties are preferred to growing numerous kinds, and the sorts of Apples chiefly depended upon are Lane's Prince Albert, Ecklinville Seedling, Worcester Pearmain, King of the Pippins, Duchess of Oldenburg, Peasgood's Nonsuch, Warner's King, and Frogmore Prolific; these were selected from many varieties that were given a trial. Of Plums, Victoria and Pond's Seedling are most remunerative, the former being most valued. The trees, like those of Apples, are well grown and in perfect health. My experience with Plum trees is, that when young they bear good crops of fruit sooner upon light soils than they do upon that which is heavy, but that they are not so long lasting; and I shall be much interested if Mr. Lee Campbell's plantation is an exception to this rule. However, at present there is no indication of the trees giving out. Pears are not wholly satisfactory, their fruits not being without blemish, as is the case with the Apples. The heaviest croppers are Louise Bonne of Jersey, Beurré Goubault, Beurré Clairgeau, Marie Louise d'Uccle, and Souvenir du Congrès. As fertilisers, chemical manures, containing a large percentage of potash, are chiefly relied upon, and these are easily applied.

In going with Mr. Campbell through his plantation when fruit-picking was being attended to, I noticed now carefully the fruits were separated, two lots being made, and each packed in different sets of baskets, under the appellation of firsts and seconds; and herein lies one of the necessary precautions to prevent a bad sale. By attention to matters of this kind, Mr. Lee Campbell never fails to secure good prices, and foreign competition is of little concern to him, as may be imagined, when I say that last year his Peasgoods' commanded in Manchester 30s. per cwt. at a time when first-rate American Apples realised only 19s. 3d. per cwt., the salesman saying at the time that he could take 100 tons per week of fruit of a similar description. *Thomas Coomber.*

THE CULTIVATION OF HENEQUEN FIBRE IN YUCATAN.

ONE of the most interesting and practical Foreign Office Reports is that which has recently been published on the Henequen Hemp industry in Yucatan. Though there seem to be several varieties of the *Agave rigida* known in Mexico, it is stated that only two are cultivated, which are easily distinguished, and bear the names of "Sacqui" or White Hemp, in which the leaves are of a light green colour with a silvery appearance in sunlight, and the "Yaxqui," with dark green leaves. The first-named is the kind almost entirely cultivated in Yucatan, a small portion only of the second being grown, and that principally in the eastern part of the State. Regarding the area of land under Henequen culture, though there is a good deal of difficulty in arriving at anything like an accurate estimate, it is calculated that it occupies about 350 square miles, and it is further estimated that for the present year, 1892, from January to December, the exports of Yucatan Hemp would amount to about 350,000 bales, each bale weighing about 375 lb. A Hemp plantation lasts for some fifteen years, as a general calculation, on the basis of production for each mecate of 100 lb. From the time of planting-out of suckers until they produce, five years as a rule, are required. In good

land the crop commences in four years or earlier, whilst on rocky ground six years or more. These calculations are based on the planting-out of suckers under the same conditions in both kinds of ground with plants of from 18 to 20 inches long. Hemp planted on fertile land produces less weight of fibre, although it is longer and finer, because on rocky soil the roots run along the surface instead of penetrating into the ground.

Although new plants are being continually placed with the old ones, it is considered that no more than the 350 square miles will be cultivated, as old plants are always dying out. The only chance of a larger area coming under cultivation is from immigration, and this is extremely difficult, owing to the great heat of the climate. The plants can be produced from seeds, but the system is never used in Yucatan, in consequence of the length of time before the plants come to maturity, suckers are, therefore, always planted. The system of cultivation is very simple, the young plants already referred to, from 18 to 20 inches high, are planted in straight lines, leaving lanes between usually from east to west, more from custom than any known reason or cause; eighty-four plants to the mecate is considered the most convenient, both for the working and the growth of the plants. Rocky ground is the most favourable, and the only preparation made for sowing the Hemp is to clear the ground of trees and plants, the former serving to make charcoal. The first crop sown on the ground so cleared, is Maize, this being the quickest crop. This gives time for farmers to rail-in their ground until Hemp is ready to take the place of Corn. The farms are divided by stone walls, as there is a good supply of stone on the land. Then the plantations are laid out in straight lines with the usual number of plants per mecate, according to the extent of land disposable, and in the most convenient manner for taking the leaves when cut to the cleaning-machine; on the majority of the farms portable railways have been laid. On most farms the ground is cleared of weeds twice a year, and on others three times, according to the class of ground, the means of the farmer, &c. There is no fixed rule as to the right time of cutting the leaves, and on this point no certain reason can be given. Opinions differ as to the proper time, and the Indian servants only seem to know when the leaves are ripe for cutting. In cutting the leaves, the usual custom is to take from each plant, commencing from below, some few leaves in the first year of production, and afterwards some twenty-four leaves from each plant. If from want of labour the farmer is obliged to cut more leaves from each plant at one time, he tries not to cut more than twelve. Too much cutting kills the plant very soon; on the other hand, plants cannot be left without cutting the leaves when ripe, as by cutting the plant continues producing. As soon as the plant begins to flower it ceases to produce leaves, and should be destroyed, as the seeds are of no use in established plantations.

In order to go on replacing plantations without special expense, and in order not to change the form or work on same, it is the custom to place at the foot of each plant when about three-fourths of its life are spent, a small plant, which latter, when the old one gives out, is ready for production. There are several opinions as to the best means of planting the suckers, although in general, they are taken from the old plantations, and at once placed in new plantations. Trials have been made, and with satisfactory results apparently, of leaving the suckers before placing them in fresh plantations in heaps in the open for some two months or more, placed so as to receive the full heat of the sun on the base of the plant (in form like an Onion), from which the roots are taken off. On being taken to new plantations, the base is peeled, and any dry roots removed, and all dry leaves thrown away. Although the suckers are apparently ruined by this exposure, and for the first two years present a very poor appearance, looking completely dried up, yet in the third year they regain such strength in growing that they then

are superior to plants placed out fresh—that is, planted out direct from the old plantation to the new one; and this advantage is seen by their producing more leaves, and those stronger and larger than the other plants. When farms have no old plantations from which to gather the necessary suckers of 18 to 20 inches high, they are produced by providing space for small plants or seedlings; these are placed in the ground, as if they were vegetables, with from 4 to 5 inches of leaf, and planted in rows about 3 or 4 inches apart, and some 10 or 12 inches between each row, the distance being regulated by the size of the plants. On planting-out seedlings, the roots are taken off. In making new plantations it is better to leave these seedlings exposed for a period of from eight to fifteen days before planting them. They have to be watered now and again, but only sufficiently to keep the ground from becoming too dry.

The machinery mostly used for extracting the fibre is the rasping-wheel made by Messrs. Death & Ellwood, of Leicester, who also furnish other machinery, but for some time past the farmers only buy the principal piece, the wheel, which is 40 inches in diameter. The great increase in the cultivation of the plant has caused farmers to look for quicker means of extracting the fibre, as many have oversown and are unable to attend properly to what they have sown, and the scarcity of labour tends to increase this need; but although much study has been given to the matter, only amongst the larger farmers who can stand the expense, can new machines be employed, such as will compensate for the want of labour. The wheel above-mentioned, with two men for direct management, can clean some 9000 leaves per day. The pressing of the fibre into bales is done on the farms by means of lever or screw-presses by hand or by hydraulic pressure. The screw-presses are of American manufacture, and the hydraulic are English.

The principal markets to which the Hemp is now sent, are as follows:—United States, principally through New York and Boston; New Orleans is also taking considerable quantities, and there is a probability of Philadelphia becoming a direct importer. The imports to England come chiefly through Liverpool, those to France through Havre, Germany through Hamburg, Cuba by Havana, and Spain by Seville, Alicante, and Barcelona.

THE ROSERY.

NEW ROSES AT THE NATIONAL ROSE SOCIETY'S EXHIBITIONS OF 1892.

It is always interesting to lovers of the Rose to have a few notes upon the various good or bad qualities and characteristics of the newer introductions among the queen of flowers. Probably there are no better opportunities of making reliable notes so far as the newer productions are concerned, than that afforded by a careful look round among those exhibited in the classes for new Roses at such large and representative gatherings as are held by the National Rose Society, both in the metropolis and at various places throughout the country.

This year the two annual shows were held at the Crystal Palace and at Chester, and new Roses were well represented at both meetings. It will perhaps be well to deal with them in the same order as they appear on my notes, irrespective of the class or section they represent.

I will, therefore, commence with the class for twelve new Roses at Chester on July 16. The lot gaining the first prize, and shown by Mr. H. Merryweather, Southwell, Notts, was a really pretty lot for "new Roses." Gustave Piganeau was, of course, the best in the box, and I will dismiss this sort as soon as possible by merely saying it is in every way a grand Rose. Out of the four Silver Medals offered for the finest hybrid perpetual Rose at these two meetings, Gustave Piganeau took two. When I remind my readers that this was against the competition of all the leading varieties, many of which

are grown in tens of thousands over the country, I trust they will see how much extra honour attaches to a new Rose through winning in such company. This Rose has also not had the chance to do itself justice from strong and established plants, as it was only introduced to general commerce in 1889, and, like other good new Roses, has been strained somewhat through over-propagation.

Jeannie Dickson is another splendid new Rose of great promise. Grand in growth and habit, perfect shape, and a sweet colour, but not quite so full as our first-class varieties should be to keep up the general standard of excellence.

Bruce Findlay was also worthy of note. This is a very bright crimson, flowers large and well-shaped, but not over full. It will rank among our best autumnal Roses, being very free, and possessing much of the characteristics belonging to the China Roses.

Mrs. Watson has grand shell-shaped petals, is a very large flower, pale pink in colour, and of vigorous growth.

Medea has a soft lemon colour for its ground, with a deep canary-yellow centre. It is clear, large, full, and globular. The growth is vigorous, and the Rose has much promise.

Marchioness of Dufferin is a very large flower, that possesses a particularly soft rosy-pink shade. I have noticed this Rose several times during the present summer, and each time it has advanced in my favour.

Denmark gives one an idea of being too much like one often sees as La France to be considered so thoroughly distinct as one could wish. It is a very promising Rose in all other respects.

Margaret Dickson is undoubtedly one of the finest white Roses we have. It is of very similar habit to Merveille de Lyon, and is said to be an improvement upon this grand white hybrid perpetual. At Chester the raisers, Messrs. A. Dickson & Sons, of Newtownards, Ireland, showed forty-eight superb blooms not for competition. I can speak of this Rose from personal experience, and may say it is in every way first-class.

Salamander, as its name would imply, is a very deep and vivid scarlet; this is brighter in the summer, but more deep coloured and glowing towards the autumn. The flowers are large and full, with an upstanding centre, surrounded with large petals that are finely reflexed. It is free-flowering, has very pretty foliage, and seems to enjoy a good constitution.

J. B. Varonne is a very pretty Tea-scented variety, and of a most peculiar and pleasing colour. With much of the metallic hue to be found in L'Idéale, and with some of the pretty tints upon the outside of the petals in the way of Madame de Watteville, this new Rose is certain to become a favourite among the ladies.

Caroline Testout is a hybrid Tea that I have seen very good more than once this season. At the Temple Show, in the spring, this was shown well upon pot plants, and is evidently a grand Rose for forcing. In colour and habit it partakes of the old favourite La France, but is a trifle deeper in colour than that Rose generally comes with me.

Princess May is a wonderfully pretty Rose. I am doubtful if it is a Tea-scented or hybrid Tea variety. This was also seen at the Temple Show, and from its habit of growth, and handsome foliage, combined with a combination of delicate peach, flesh, and salmon colours in the bloom, I have no hesitation in saying is a grand acquisition.

Duchess of Marlborough is a very sweet-scented variety, deep rose in colour, flowers large and globular. Very distinct.

Marchioness of Lorne has come particularly well with me upon maidens this season, and is a good all-round Rose. Colour red, with a slightly carmine centre; it is very free-growing, and a profuse bloomer.

Mrs. Paul is the grandest Bourbon Rose we have after Souvenir de la Malmaison. This is a large open flower, with the outer petals slightly reflexed, in the style of a Camellia. It is a fine exhibition

Rose of its class, as the petals are stout, and perfectly arranged. Colour blush-white, with a slight rosy-peach shading.

Triomphe de Pernet Père is a grand hybrid Tea, of much stronger, and more satisfactory growth than the majority of this class; it has a long bud, vivid red in colour, and is very free blooming.

Waban is another American sport from Catherine Mermet; it is said to be larger than its parent, but it has failed to come so with me, nor have I seen one near that size. The flowers are a good shape, and very much resemble Catherine Mermet, except in being a deeper red. I expect it to turn out much better than I have seen it as yet.

Henry Gow is a cross between Star of Waltham and President Léon de St. Jean. From the grand plant exhibited at the Crystal Palace, it is evidently a good grower and free bloomer. The blooms are of fairly good shape, but the colour is not distinct enough from Star of Waltham to recommend itself to me as a good new Rose.

Spenser is a good flesh-coloured Rose, of great substance, and when young it possesses the same shape as Baroness Rothschild. It opens into a flat flower, of the Malmaison type, too quickly to become a popular exhibition Rose; but for pot work, or as a garden variety, it is evidently one of the best. At all of the principal shows, this new Rose has been shown fairly well.

Gustave Regis is classed by the raiser as a hybrid Tea, but it gives me the impression of being as pure a Tea-scented variety as Sunset, a Rose that it resembles in colour. It is not heavy enough for exhibition, but is undoubtedly a good Rose for forcing and general cut flowers.

Corinna is not so globular as Grace Darling, is of much the same style and colour, and a very pleasing little Rose.

May Rivers has the same grand habit and bold flowers as The Bride and Elith Gifford; in colour it partakes a little of both, and is a grand new Rose.

Lady H. Grosvenor is a hybrid Tea of similar growth and habit. This bloom, however, has a deep tinge of salmon-pink in the centre, somewhat like a very fresh flower of Souvenir de Paul Neyron. Like the last-named, it goes flat very early, but it is a good Rose for garden cultivation and cut flowers.

Mrs. W. J. Grant was shown in competition for the Gold Medal of the National Rose Society, both at the Crystal Palace and at Chester. In the former case it was unsuccessful, but easily carried off the honour at the latter show. It is a grand Rose, and as shown at these two meetings, evidently varies a little in its character. Those exhibited at Chester were far superior to the blooms staged at the metropolitan show. Jeannie Dickson, Mdlle. Eugénie Verdier, and La France combined may perhaps be as true a description of this Rose as any. I was much struck with the grand shape and substance of the best bloom of this at Chester.

There are a few new Roses that are not yet in commerce which are certain to be heard of in the near future. Three of the best of these, and which have already been exhibited in competition for the Gold Medal, were—

Mrs. Arthur Wilson, a pretty Rose of a deep, and yet bright pink colour, a shade between Mrs. G. Dickson and Mrs. John Laing. It is not very full, and I will dismiss it with the few words written on the card by the judges: "Think well of it, and would like to see it again."

Merrie England is a sport from Heinrich Schultheiss, and is one of the prettiest and most unique Roses grown. It is irregularly striped or flaked with deep rosy-red upon a salmon-flesh ground, very much in the same way as a Carnation.

Mrs. Harkness is another sport from the same variety. This is a self colour of a pale and very delicate satiny-flesh shade, quite distinct from any other shade among Roses. Both this and the former sport are of equally good habit and sweet scent as the parent variety.

Messrs. A. Dickson & Son, of Ireland, have been sending out a good strain of Roses during the last few years, and I noticed four unnamed seedlings in

one of their competition boxes at Chester that were of similar type to Mrs. J. Laing and Gabrielle Luizet, and if they are equal to these Roses in other respects, they are sure to be acceptable to the Rose-loving public. A. P.

PLANT NOTES.

PLUMIERA RUBRA.

ALTHOUGH this is a very old Apocynaceous plant, having been figured in the *Botanical Magazine*, 8th vol., t. 279, yet it is not often seen in flower. It is a native of the West Indies and South America, and the genus was named after Plumier, a French botanist and traveller. The stems are tall and thick, and together with the leaves contain a quantity of milky sap. The plants are deciduous through the greater part of the winter, and at such time require to be kept somewhat dry. Water should be given plentifully when the plants are growing. Propagation may be effected either from seeds or by cuttings, the latter being allowed to dry before insertion. The flowers are produced at the apex of the stems in clusters; the corolla is funnel-shaped with a long tube, dull red shaded with rose, curiously sweet-scented. Its common name in the West Indies is "The Red Jessamine." This plant is generally grown in a stove temperature, but a plant, 4 feet high, is at present flowering in the Cactus-house at the Royal Gardens, Kew. *Lodoicæ*.

THE WEEK'S WORK.

THE FLOWER GARDEN.

By H. W. WARD, *Gardener, Longford Castle, Salisbury.*

HARDY PERENNIAL FLOWERS.—Now that the beauty of the summer bedders is over, the charm and freshness of the different kinds and varieties of herbaceous perennial plants still continue to please, if those exist in any quantity in the garden proper, and more especially when they are contiguous to the dwelling. I will indicate by name a few of these—*Aster formosissimus*, rosy purple; *A. laevis*, lilac, with yellow centre; *A. novæ-angliæ*, bluish-purple; *A. Robert Parker*, grey; *A. albus*, white; *A. versicolor*, white, shaded with pink and lilac; *A. Amellus* *besarubicus*, bright purple with orange centre; *A. pulchella*, light purple; *A. dumosus*, rosy-purple; *Helianthus multiflorus maximus*, numerous yellow flowers about 4 inches in diameter; *H. giganteus*, growing to a height of 7 feet, with yellow flowers; *Rudbeckia Newmanii*, large golden-coloured *Marguerite*-like flowers, a most useful plant for cutting from. *Betonica grandiflora*, producing a profusion of small white flowers; *Senecio Doronicum*, yellow; *Solidago* (Golden Rod), *Gaillardias*, *Achilleas*, and *Montbretia crocosmaeflora*, with erect spikes of deep orange and scarlet flowers, a bulbous plant, which should find a place in most gardens. Some other capital plants are *Anemone japonica* in its two forms; *Aconitum autumnale*, *Lobelia cardinalis*, *Phloxes*, and *Pentstemons*.

RHODODENDRONS, KALMIAS, AND AZALEAS.

The present is a good time of the year to make or prepare for the planting of beds of American plants, and to fill up vacant spaces, or plant new beds, &c. In planting the choicer *Rhododendrons*, it is necessary that the soil should be of a suitable nature, either peat, very light loam of a fibrous nature, i.e., a soil full of the roots of Ferns, grasses, &c., dug out to a depth of 2½ feet. The staple should be replaced with a compost which may consist of three parts of good peat or fibrous loam, and if peat be used, one-fourth may be added of sound loam, the ingredients being chopped up roughly and well mixed together before being wheeled into the hole. The plants, if from a nursery, are usually small, and may be provisionally planted about 2 feet apart, the soil being trodden firmly about them, and a heavy watering afforded them, repeating the watering at short intervals in the absence of heavy rain till the roots have pushed into the new soil. Among the many fine varieties of *Rhododendrons* in cultivation, mention may be made of the following:—*R. Alarm*, white centre, edged with crimson; *R. Barclayanum*, rosy-crimson; *R. candidissimum*, blush; *R. coriaceum*, pure white; *R. Nobleanum*, crimson; *R.*

Marchioness of Lansdowne, pale rose, with black spots; R. Lady Olive Guinness, white, spotted chocolate; R. Lady Skelmersdale, pure white, trumpet-shaped flowers; and R. Lady Eleanor Cathcart, having pale rose flowers, spotted with chocolate.

FRUITS UNDER GLASS.

By J. RIDDELL, Gardener, Castle Howard, York.

MELONS.—At this season the plants do not exhibit the same tendency to grow away, as is the case at midsummer; nevertheless, it is equally important now, as then, to check exuberant growth, in order that the fruits may have as much of the declining sunshine as possible, as an aid to ripening and for imparting flavour. Afford the plants sufficient water at their roots to enable them to carry their fruits to the finish, but avoid supplying it on damp days, it being essential that a dryish atmosphere be maintained in the Melon-house or pit, and especially necessary to prevent the splitting of the fruits. The colder nights now will require a larger amount of fire-heat to be employed, and this, combined with the other altered conditions, as compared with those of the summer, will favour the increase of such insects as infest the Melon; keep, therefore, a sharp outlook for the enemy. Apply the usual nostrums to dispel them, if present, syringing with soapy water for red-spider, on some bright morning, when, with the ventilators open, the circulating air will carry off the excess of moisture before nightfall. In dull weather sponge the foliage rather than delay the job. Maintain, in average weather, a minimum temperature of 75°, and on very cold nights allow the warmth to fall 5° by the morning, which is better for them than much artificial heat.

TOMATOS.—Melon-houses that are cleared of their plants may be utilised for any Tomato plants which may have been grown in pots out-of-doors, previously washing the woodwork and glass with soft soap and hot water, using a hand brush. Remove also all the exhausted hot-bed soil, if it interfere with the position of the pots or plants. In most cases it will serve the purpose of a stage to stand the pots upon. Tie the Tomato plants loosely to the bottom wire, by way of making allowance for the bed settling. Keep a dry buoyant air in the structure. Well attend to stimulating the plants with phosphatic manures if the soil in the pots has become rather exhausted, and frequently shake the clusters of bloom to assist their fertilisation. These various details of Tomato culture are of importance at this season if a good set of fruit is to be obtained before winter is much advanced.

PLANTS UNDER GLASS.

By R. MILNER, Gardener, Penrice Castle, Swansea.

THE CONSERVATORY AND GREENHOUSE.—At this season of the year these structures should be put in a thoroughly clean state inside and out, and any repairs that may be required finished forthwith. Climbing plants on walls, pillars, and rafters, should be looked to, and strong growers, like *Cobæa scandens*, *Passifloras*, *Tacsonia Van Volxemi*, &c., should have the shoots thinned out, so that the plants beneath or near them may not be robbed of much light during the winter. In the case of *Lapageria rosea*, which at the present time will be in flower, care should be taken not to damage the latter, but should insects infest the plants some means must be taken to clean them by sponging or otherwise, but leaving the thorough overhauling of the plants till the flowering season is past. Shading material which is removable, may now be taken down, and when it is dry, put into store for the season. Large Camellias and Orange plants which may have been standing outside, and which form part of the furnishing of the conservatory, should have their leaves and shoots cleaned of scale and dirt, and the pots and tubs washed or repainted before removing them inside. Should the buds have set too thickly on the Camellias, thin to about three on each shoot.

Supposing the directions given in previous Calendars have been carried out, there will be an abundance of flowering plants for the supply from now onwards. Early-flowering Chrysanthemums will make a good show till the late-flowering varieties come into bloom. Zonal Pelargoniums struck early in the season will be showing a quantity of bloom, and the plants should be assisted occasionally with some well-tried fertilisers. The late-flowering fibrous-rooted Begonias will now be found of much use, and by placing them at the warmer end of the house they will enhance the general display for some time to come. The late-flowering Fuchsias, if they

have been assisted with manure water, should be in full bloom, also *Celosias*, *Mignonette*, *Heliotrope*, *Nicotiana glauca*, *Cassia corymbosa*, and the early-flowering *Primulas*, and these, with the addition of *Coleus*, *Ferns*, *Palms*, &c., will give a gay appearance to the houses for some time longer.

THE KITCHEN GARDEN.

By G. WYTHES, Gardener, Syon House, Brentford.

WINTER CAULIFLOWERS.—These will be ready to plant out under hand-glasses on a south border or in frames, and though the first is sometimes objected to because early plants can be raised in heat by sowing in January, I have a preference for it. The plants that are raised early in heat require a lot of hardening off, and careful protection at a busy time; moreover, the autumn-raised ones are the earlier if not cosseted in any way, as they certainly are firmer and heavier. The selected spot should have been heavily manured and trenched, a good surface-dressing of soot or lime being afforded before the planting is begun; wood ashes are good fertilisers, and may be plentifully used. Rake the border after treading all over, and put the hand-lights on beds about 3½ feet wide, with 2-foot alleys between; put nine plants under a glass. If possible, let the border be on a south aspect, more plants being lost from cold and damp soil than from actual frost. The tops need not be put on the glasses unless heavy rains occur, as if placed crossways over the top, the protection will be sufficient. Even in winter the top should be removed early on fine days. When nine plants are planted, five may be removed early in March, leaving the four corner ones to bring heads in May, those lifted forming a succession. To make sure, I put up a few hundred plants, and, should no losses occur, these are of use, as it is seldom one gets too many early Cauliflowers. Those who have not frame convenience for plants in pots may place them at the foot of a south wall, and with a slight protection these plants will give a supply in advance of those raised in heat.

BETROOTS AND CARROTS.—Though a few degrees of frost may do no harm, it is best to store these roots before winter sets in. For late spring use, and to furnish usable roots till the Egyptian Beet comes into use, there is none better than Dell's Crimson, a small-rooted kind, that keeps till very late in the spring; but plenty of earth, clean sand, or coal-ashes, should be used in the stacking of the roots. I like stacking the roots best, providing an outhouse or store just sheltered from rains is used; the cooler the better. When stored in the open, the roots should be laid in trenches, upright, soil a few inches deep being put above them, and over all a layer of litter in severe weather.

Carrots, when stored as a lished for Beetroots, are comestable at any time; but if stored in trenches in wet soil, they do not keep well. Parsnips are much better left in the ground and dug up as required, merely strewing the ground with litter to keep out very severe frost. Turnips sown for late autumn and winter consumption should be stored in the open air in ridges covered with mould, or the roots may be placed against a wall with their tops pointing outwards, 4 inches of soil being put between the different layers, and some litter in hard weather laid over all. Medium-sized roots should be selected in preference to larger ones, the latter being bad to keep. Salsafy and Scorzonera, and Chicory, should be treated like Parsnips.

THE ORCHID HOUSES.

By H. A. BURBERRY, Orchid Grower, Highbury, Birmingham.

WATERING THE PLANTS.—The time is now coming when the application of water to the roots of Orchids will be a matter requiring careful thought and consideration. I have sometimes seen plants so shrivelled by drought as to be beyond recovery, and, on the other hand, I have seen them suffering from the effects of too much wet. Remarks have previously been made in reference to those species that desire exceptional treatment during their resting period; we will now take those which flower freely under an ordinary amount of care in this respect, as, for instance, the *Cattleyas*, *Anguloas*, *Calogynes*, *Lælias*, some of the *Oncidiums* and *Odontoglossums*, or, any other Orchid which has a definite resting season. When the new pseudobulbs of those are matured, a less amount of water is needed to consolidate; but to lay down a rule hard and fast is by no means my intention, because it is not practicable. What are required are discretion, judgment, and observation as to the state of the weather, the size of the plant, and whether in delicate or

robust health; in bright weather, or when a good deal of fire-heat is used, a plant might want water once a week, whereas, if the conditions were in an opposite direction the same plant might go for a month without water. Again, a plant in a large pot, having a huge mass of material round the roots, will not require water nearly so often as one in a small pot; or one portion of the house may be naturally dry, whilst another part may have reverse tendencies. It is well for most Orchids to be kept in a dry state whilst inactive, but it must not be overdone. These are a few matters which must be duly considered in the treatment of Orchids during their resting season.

GENERAL REMARKS.—The roller blinds will now rarely be used, and where not required again they should be taken down and stored in a dry place. *Cattleya aurea*, the most lovely of all *Cattleyas*, should after flowering be placed in a dry part of the house, and the sheaths opened down, as it is very apt to rot. *Odontoglossum grande* is just beginning to make a show. These generally used to be grown with the *O. Alexandræ*, but they appreciate more warmth. *Vanda cœrulea* should not be allowed to carry its flowers too long, but the spikes should be cut off, and placed in water. They will last a long time thus, and the plant will be greatly relieved. After flowering, this *Vanda* should have an airy place in the *Cattleya*-house for the winter, and if afforded a good rest, by being kept somewhat dry, it will keep healthy, and grow well another year. *Cattleya citrina* should be grown in an intermediate temperature during winter, as it is during this season that growth is made, and too much cold will cause a black spot to appear on the leaves.

THE HARDY FRUIT GARDEN.

By H. MARKHAM, Gardener, Mereworth Castle, Maidstone.

GATHERING AND STORING APPLES.—Such of these as are not good keepers will now require to be gathered from the trees; but varieties which keep a length of time should for some time longer remain on the trees, or they will shrivel in store, and be of poor flavour. All of the Codlin type are amongst the first-named, and are fit for early use only. Even these should be carefully dealt with. When gathering and storing them, it is always better to assort the fruit into two samples, the smaller and deformed ones to be consumed first, and the finer specimens, and these should be kept apart. No fruit should be gathered of which the seeds are becoming of a brown colour. Lord Sudfield, Lord Derby, Ecklinville, Yorkshire Beauty, Worcester Pearmain, are among those that should be gathered forthwith—at least, in the warmer parts of the country. Before putting a fruit into the fruit-room, thoroughly sweeten and clean it in every part. If space is inadequate, the fruits may be put in layers of three or four deep; but the late keepers, and especially the choicer varieties, should not be piled one on the top of the other. Remember to gather fruit when it is quite dry. Apples will keep best, and retain their plumpness longest, in a cool, rather moist place, so long as the frost is kept out of it; but Pears, on the contrary, should be kept somewhat warmer—at least, those about to ripen should be, as they then acquire their fullest flavour.

PEARS.—As these become fit gather them, beginning with Marie Louise, Doyenné du Comice, Comte de Lamy, Pitmaston Duchess, Emile d'Heyst, Thomson's, Beurré Superfin, Darondeau, which are all of them Pears of the first rank. The season of these may be prolonged if the fruit is gathered at intervals. Glou Moreau, Passe Colmar, Winter Nelis, Josephine de Malines, Olivier de Serres, Easter Beurré, and other late ripening and late keeping varieties should be left on the trees as long as it is safe, say to the middle and end of the month. Keep all the sorts of fruits correctly named when in store, giving also the dates when they were gathered, began to come into use, and the length of time that each variety keeps in a usable condition.

LATE PEACHES.—Where these are still unripe, they will not be of the best quality; but it is possible to make them of passable flavour by placing them in a dry warm but airy glass-house to ripen, if the weather is cold and sunless. They may also be forwarded in ripening by putting some frame-lights in the front of the trees, leaning them against the wall—a method of protection that helps only the lower half of a tree.

GRAPE VINES.—Shorten back all side-shoots of any length; remove a few of the leaves, and more especially of white varieties of Grapes, and afford the Vines protection on cold nights.

APPOINTMENTS FOR THE ENSUING WEEK.

MEETINGS.

- TUESDAY Oct. 4 Meeting of the Fruit and Floral Committees of the Royal Horticultural Society, at the Drill Hall, Westminster.
- FRIDAY, Oct. 7—Dundee Horticultural Association.

SHOWS.

- TUESDAY, Oct. 4 Show of Michaelmas Daisies and Hardy Herbaceous Flowers, at the Drill Hall, James Street, Westminster.
- WEDNESDAY, Oct. 5 Great Show of Hardy Fruits, Potatoes, &c., at Earl's Court Exhibition (three days). Mayfarth's Fruit Drying Apparatus will be exhibited at work in the Royal Horticultural Society's Garden, Chiswick, from 10 A.M. to 4.30 P.M.

SALES

- MONDAY, Oct. 3 Clearance Sale of Nursery Stock and Greenhouses, at the Heaton Norris Nurseries, near Stockport, by Protheroe & Morris (four days). Great Sale of Dutch Bulbs at Protheroe & Morris' Rooms.
- TUESDAY, Oct. 4 Sale of Plants from Belgium, Carnations, &c., at Protheroe & Morris' Rooms.
- TUESDAY, Oct. 4 Sale of Dutch Bulbs at Protheroe & Morris' Rooms.
- WEDNESDAY, Oct. 5 Sale of Dutch Bulbs, at Protheroe & Morris' Rooms. Extensive Sale of Orchids, at Messrs. Seeger & Tropp's Nurseries, East Dulwich, by Protheroe & Morris. Dutch Bulbs, Lilies, &c., at Stevens' Rooms.
- THURSDAY, Oct. 6 Dutch Bulbs and Plants, at Protheroe & Morris' Rooms. Important Sale of Nursery Stock, at the Chilwell Nurseries, Notts, by Protheroe & Morris. Dutch Bulbs, Lilies, Orchids, &c., at Stevens' Rooms.
- FRIDAY, Oct. 7 Nursery Stock, at Ponsford's Nursery, Brixton, by Protheroe & Morris. Orchids, from Mr. F. Sander, at Protheroe & Morris' Rooms. Dutch Bulbs, at Protheroe & Morris' Rooms.
- SATURDAY, Oct. 8 Dutch Bulbs, at Protheroe & Morris' Rooms. Dutch Bulbs, Lilies, &c., at Stevens' Rooms.

CORRECTED AVERAGE TEMPERATURE FOR THE ENSUING WEEK, DEDUCED FROM THE OBSERVATIONS OF FORTY-THREE YEARS, AT CHISWICK.—53°.6.

Those who are fortunate enough to have visited this unique seaside resort will recognise the "invalid's walk," shown in our illustration (fig. 65). It forms part of a valley which runs direct from the sea-margin inland for a distance of $1\frac{1}{2}$ mile or more, till it loses itself in the moorland characteristic of Dorsetshire. This valley justifies the use of the term unique, for where else can there be found such a valley, running, as this does, right through a populous town? where else can such a transition be seen from the barren sea-shore to the Pine woods, the ornamental shrubberies, the well-kept lawns and flower-beds in the very centre of the town, and thence gradually merging into the vegetation of the wild moorland, so attractive to the plant-lover? The transitions are really remarkable, and remind us, on a small scale, of the gradual change in the vegetation which the traveller meets with as he gradually ascends some alpine valley from the warm plains to the regions of snow and ice. Nor can we but admire the ingenuity with which a little trickle of water is made to look like a flowing river—a very tiny one—suggestive of Chinese gardening.

In spite of its diminutive proportions, it is pleasing to the eye, and the source of infinite gratification to the children who take as much delight in the sailing of their toy-boats in the brown streamlet as their seniors in the performances of their yachts in the green-waved Solent. This stream is confined within bounds in the dressed garden, stiff and formal in outline as if it were on its good behaviour; but gradually, as it nears its source, the canal gives place to a rivulet with its irregular margin bedecked with Forget-me-Nots and other wild flowers. The whole stream is so tiny, that one can hardly resist smiling at it; but it is so pretty, and so much pains have evidently been taken to make it look well, that we can but congratulate the authorities on difficulties overcome, and trust that in due time an abundant reservoir may be at their disposition, and enable them to do even better.

The prominent feature of Bournemouth is, of course, the Pines—they are everywhere, young and middle-aged trees, principally Pinasters and Scotch—who could have planted such a vast area? All honour be to him. He planted for posterity, but posterity is at least appreciative. The Pines, as is their nature, are getting scraggy, and it behoves the authorities to plant others to take the places of those which are prematurely old, and to infuse a little variety of form and colour. *Pinus insignis*, *P. densiflora*, *P. laricio*, *P. austriaca*, *P. contorta*, *P. montana*, *Cupressus macrocarpa*, *C. sempervirens*, *C. lusitanica*, *C. Benthami*, *Cedrus atlantica*, the Douglas Fir, are a few that occur to us as we write which would in all probability bear the sea breezes and thrive on the sandy soil of Bournemouth. Whether the silver firs and spruces would do equally well we do not know.

Rhododendrons form the chief under growth, and a magnificent appearance they present in June, even within a stone's throw of the sea, and "just across the street." The quantities in the valley and in the neighbouring chimes are prodigious, but here, again, a little more variety of colour would be acceptable, and some of the finer-coloured sorts might be mixed in with the too prevalent Lilacs.

The lawns in the central part of the garden nearest to the streets are gay with flower beds appropriately enough, but elsewhere it is a pity to break up the sweep of the lawn with such impertinences. In the shrubberies, *Escallonia macrantha*, as generally by the sea, forms a splendid evergreen, with its deep rich foliage, and spikes of bright pink flowers. In June, too, the single *Viburnum opulus* made a great display. In the mass, it is less effective than the common Gueldres Rose, but the individual flower-heads are more attractive. The common Bird Cherry was also particularly beautiful. Laburnums, Lilacs, *Buddleia globosa*, *Weigela*, *Lycosterias*—these were among the most showy of deciduous plants; whilst amongst evergreens, in addition to the ever-present Pines, there were Portugal Laurels, Darwin's *Berberis*, resplendent with orange and bronze flowers; *Daphne pontica*, Hollies, Bays, *Aucubas*; and the usual occupants of the shrubbery. In front are herbaceous plants and annuals of the most miscellaneous nature, but all presenting in their flowers a richness and brilliancy of tint conferred by proximity to the sea, and never rivalled inland.

Much has been done at Bournemouth, and the oñines and moors in the vicinity are charming, each in its way. It is evident, moreover, that such situations would form excellent experimental gardens for the introduction of the more beautiful New Zealand and Californian shrubs. Perhaps also some of the Mediterranean, Cau-

casian, and even Himalayan plants, might succeed. In any case, the Bournemouth people have only a few miles' distance to go to see what may be done in the way of "acclimating" plants in the gardens of Dr. ALLMAN and Dr. WALLACE, at Parkstone, and other examples may be found in the neighbourhood of Poole.

We have ventured to make some suggestions, and we add one more, plant the East Cliffe. Gorse seeds might be sown broadcast in the sand, and a plantation of double Gorse, double-flowered Brambles, Tamarisks, Elders, Privets, Atriplex, *Halimus*, *Pittosporum*, *Euonymus*, scarlet-barked Cornel. Most of these would succeed well on the cliff, and take off that barren appearance which the coast-line now presents.

ROYAL HORTICULTURAL SOCIETY.—On Tuesday, October 4, a show will be held in the Drill Hall, and prizes will be offered to amateurs for hardy herbaceous perennials. Mr. D. DEWAR will read a paper on "Michaelmas Daisies," at 3 P.M.

"KEW BULLETIN."—The September number comprises an article on "Caraguata" fibre, which is now ascertained to be the product of *Bromelia argentina*, a native of Paraguay, and which is hotanically described by Mr. BAKER. The fibre is excellent, but there are difficulties in the way of cleaning it from gum. In an article on Lagos Palm oil, the preparation of the oil from the seeds is described and illustrated. Large as is the quantity exported, it appears that very much more is available were the resources properly utilised. Vanilla is the subject of another article. "Decads" of new plants and similar "decads" of Orchids are published, and enable the botanist to be made acquainted with the newly-discovered treasures in the herbarium.

MR. CHARLES EDMONDS.—We are sorry to hear of the death of Mr. CHARLES EDMONDS, late of Hillingdon Nurseries, in his sixty-third year, and to learn that he has unfortunately left his widow and family very indifferently provided for. Any contributions by kind friends on their behalf will be thankfully received by Mr. H. D. BEAKELY, No. 4, Gray's Inn Square, his executor.

MISS JAMESON FUND.—In addition to the sums previously acknowledged, we have received the following:—

A. B.	£5 0 0
DR. CLEGGHORN	1 0 0

THE LIME TREE MITE.—If we may judge from the specimens sent to us, this little *Acarus* is very abundant this season. The bark of the tree has a glazed appearance, as if covered with a thin layer of milk and water; on examination this appearance is found to be due to a dense web of silky fibres of extreme thinness. The mite is extremely abundant, of a pale orange colour, and about the size of the common red-spider; they suck the juices of the leaves, causing them to shrivel. Mr. MICHAEL obligingly adds the following particulars:—"The destructive *Tetranychus tiliarum* of MULLER (*Trombidium tiliarum* of HERMANN, *Flexipalpus tiliarum* of SCHEUTER) is a close ally of the red-spider of our greenhouses. Some authors have considered it only a small variety of that species, which is probably an error. See ANDREW MURRAY, *Economic Entomology*, p. 107; HERMANN, *Mémoire aptérologique*, p. 42; DONNADIEU, *Recherches sur les Tetranyques*, p. 123; SCHEUTER, *Einiges über Milben*, *Archiv. für Naturgesch.*, 1857, p. 104, &c.; ORMEROD, *Injurious Insects*, p. 140. Sulphur is the best remedy."

PODACHÆNIUM ANDINUM.—M. ANDRÉ describes and figures in the last number of the *Revue Horticole* an example of what it was once the fashion to call a subtropical plant. What was meant was a plant of bold foliage and striking appearance, suitable for the decoration of the lawn, or as a component of flower beds during the summer. Of plants of this character, none was more sought after than *Ferdinanda eminens*,

M. ANDRÉ tells us this was a misnomer, and that the plant was really a *Podachænum*. Now he adds another species, which he himself collected on the Andes of New Granada, and which he describes and figures as *Podachænum andinum*. The plant is of bushy habit, with broad-lobed leaves and prominent nerves. The heads of flowers are in panicles, the ray florets white, those of the disc yellow.

ROSE OF JERICHO.—In the *Gartenflora* for September 15 is published a figure of a Composite (*Odontospermum pygmaeum*), which shrivels when dry, to expand again if soaked in water. Our contemporary calls this the "Echte Rose von Jericho"—the genuine Rose of Jericho. Other plants having similar properties are the Crucifer,

Hunter's Hill, on August 15. Mr. FITZGERALD, who had been in the colony for thirty-six years, was sixty-one years old at the time of his decease. He was a native of Tralee, county Kerry, Ireland. Mr. FITZGERALD took a great interest in botanical questions, and was the author of an admirable illustrated work on Australian Orchids, which is a substantial contribution to our knowledge of the structure and life-history of Australian Orchids.

ORCHIDS AT HOME.—"Eria, Cœlogyne (*Wallichii*, *maculata*, and *elata*), *Cymbidium*, *Dendrobium*, *Sunipia*, some of them flowering profusely; and though freely exposed to the sun and wind, dews and frosts, rains and droughts, they were all fresh, bright, green, and strong, under very different

sepulchre as the furniture of the last resting-place of their beloved ones. Many of these floral remains are so well preserved that, after being treated with warm water, they can be handled like modern herbarium specimens. The colours, too, are preserved in a remarkable way. The most important matter in connection with these plants is their age. The remains of funeral-food are found in the tombs as far back as 3000 years before Christ. Five hundred years later grains of Mustard-seed, capsules of Flax-seed, Gourds, Lentils, Beans, Figs, Juniper-berries, and other edibles, also Pine-needles are found. The richest acquisitions in leaves and flowers to the herbarium were made from the tombs constructed between the eighteenth and eleventh centuries B.C. Among the flowers chiefly employed in floral

FIG. 65.—VIEW IN THE INVALID'S WALK, BOURNEMOUTH. (SEE P. 404.)

Anastatica hierochuntica, and the *Selaginella lepidophylla*. The soil of Jericho must be peculiar to produce such "Roses," and the topography of Jericho—or perhaps we shall do well to take the term Rose in a very broad sense indeed.

IRISH AGRICULTURE.—A Government return before us shows that the total area in Ireland under crops in 1892 is 4 888,784 acres, being a net increase over 1891 of 66 403 acres. The area under Wheat culture had diminished, but that under Oats had increased by no less than 10,911 acres. Potatoes showed a decrease of 13 390 acres—a continuous and steady fall each year since 1888. There has been an increase in live-stock generally, but a decrease in pigs.

MR. R. D. FITZGERALD.—We greatly regret to learn, from the *Sydney Daily Telegraph* of August 16, of the death of Mr. R. D. FITZGERALD, late Deputy Surveyor-General, which took place at his residence,

treatment to that to which they are exposed in the damp, unhealthy, steamy Orchid-houses of our English gardens." *Sir J. D. Hooker*, "*Himalayan Journals*," new edition, p. 500.

A DOUBLED ORANGE.—Mr. STURZ, of Porto Alegre, sends us a photograph showing complete union of two Oranges with, as usual, a partial obliteration of some of the cells or carpels along the line of junction. Such cases of synanthry or syncarpy are by no means uncommon.

THE OLDEST HERBARIUM IN THE WORLD is in the Egyptologist Museum at Cairo, and consists of a collection of dried portions of plants. These portions of plants and flowers were taken from wreaths and garlands in the coffins with mummies, where they were placed by the ancient Egyptians as death-offerings, and from edible plants which were set in earthen vessels on the floor of the

decorations for the dead were the blue and white Lotus, the red Poppy, the Oriental Hollyhock, Crown Chrysanthemum, Safflower, Pomegranate-flowers, Willow-leaves, grasses, and Peppermint. Celery-leaves came into requisition later, and Onions, Leeks, and Garlic played an important part in the offerings to the dead. One of the general conclusions drawn from this herbarium is, that Egypt has sustained no appreciable climatic changes during the last 4000 years. *Garden and Forest*.

PRUNES IN CALIFORNIA.—Some interesting particulars are given by Consul DONOHUE, of San Francisco, on the subject of the cultivation of the Prune in California. It is to France that California is indebted for this healthful and profitable fruit. LOUIS PELLIER, a French sailor, arrived in San Francisco in 1849, and went to work in the mines in Trinity county. He did not succeed well there, and

finally removed to San José early in the fifties. Here he established a nursery. He soon after induced his brother PIERRE to join him in California, and the two brothers worked the nursery together until the spring of 1856, when PIERRE returned to France in order to marry a girl to whom he was engaged. Combining business with pleasure, he secured a large number of cuttings of Prunes, Grapes, and other fruits, which he brought back with him on his return. The Prune cuttings were procured in the Villa Neuve d'Agen, from whence the Common Californian Prune derives its name of "Petite Prune d'Agen." They were carefully packed in a box about 16 inches square by 4 feet in length, which was lined with cloth, and every precaution was taken to insure the safe arrival of what has since proved the germ of one of the most important industries of California. The importance of PELLIERA's experiment was not appreciated for about a quarter of a century after he began it, but at length the superiority of California as a fruit-growing State forced itself upon public attention, and the Prune was given a trial. From that time the growth of the industry has been phenomenal. It is estimated that in California, in Santa Clara county alone, when the trees now growing shall have matured, the annual product will be over 40,000,000 lb. of dried fruit. The most extensive single Prune orchard in the State is now in the Salinas Valley, in San Luis Obispo county, on the eastern slope of the coast range, near the town of Templeton. In this orchard there are nearly 300 acres of Prunes in one body, containing 324,000 trees. The first Prunes were grafted on Plum stock, but this has grown into dis-favour on account of the tendency of Plums to throw out suckers and other stocks, the Peach, the Apricot, and, lastly, the Myrobalan Plum, have come into use. The principal markets for Californian Prunes are Chicago and New York. The quantity now consumed in the United States is enormous. It will be years before the demand on the other side of the Atlantic can be supplied, and when that shall have occurred, there will be the markets of Europe and the rest of the world to supply, for the California Prune is said to be superior to the French Prune in flavour, while it will keep better and longer, without sugaring, than the latter.

CYPRIPEDIUM SANDERSIANUM ×.—This, one of the rarest and most distinct hybrid *Cypripediums*, is now in flower at Mr. William Bull's establishment. It is the plant purchased of Mr. LEE of Leatherhead for 300 guineas, the price conveying in some measure an idea of its choice and remarkable character.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.—The annual dinner of this Society will be held on Wednesday, the 5th inst., at the Cannon Street Hotel, at 6 P.M. The chair will be taken by J. FRASER, Esq., of Lea Bridge. We trust there will be a good attendance.

LOTTERY.—Our attention has been called to the circular and ticket, of which we append a copy, and we have been asked if the matter has our sanction. To this we can only reply that we know nothing whatever of the matter, that no name is appended to the documents, and that, as a matter of opinion, we doubt the morality and the legality of such lotteries.

A GRAND DRAWING.

To raise Funds for the erection of a Boys Orphanage, under the care of the Sisters of Charity, St. Elizabeth's House, Bullingham, Hereford. Tickets, 3d. each. Several valuable and useful prizes. To be drawn November 15, 1892. Winning numbers will be published in the *Gardeners' Chronicle*, November 26, 1892.

Dear Sir,

This little Lottery is exclusively amongst the Gardeners of England and Wales, we trust therefore to your Charity, that no one will refuse to take or dispose of the enclosed tickets; though the sum of 2s. 6d. may appear small, the help to us will be great. We pray God to bless all Benefactors. Anyone taking or disposing of four books of Tickets (09s. worth) will be entitled to a Ticket for the All Prize Drawing."

QUEENSLAND FERNS.—Mr. F. M. BAILEY, the Colonial Botanist of Queensland, has published a series of lithographic illustrations of the Ferns of that colony. The work is published under the auspices of the Department of Agriculture, and is intended for the Fern-lover rather than for the student. The plates number 190, and are sufficient for the purpose. The name of each Fern is given, together with an indication where the plant is described in full. An alphabetical index supplies the synonymous and vernacular names, so that the work, though unpretending, is calculated to be very serviceable.

TREATMENT FOR SMUT IN OATS AND WHEAT.—The September *Bulletin* of the Michigan Agricultural College contains an account of the heavy losses caused to farmers by smut in Oats and Wheat, and describes the Jensen, or hot-water method of treatment for the same. For Wheat, the following treatment should be adopted:—"Have two kettles of water, not more than 2 feet apart. Kettle No. 1 should contain warm water (from 110° to 130° F.). The water in kettle No. 2 should be heated to 135° F. The first is for the purpose of warming the seed preparatory to dipping it into the second. Unless this precaution is taken, it will be difficult to keep the water in the second vessel at the proper temperature. The seed to be treated should be placed in a sack that will allow the water to pass through readily (a coarse gunny sack is good). According to the size of the kettle, the sack may contain from one-half to 1 bushel. A less amount will make the process slow, and a larger amount will be unwieldy, and some of the kernels may escape treatment. Dip the Wheat into kettle No. 1, lifting it out, and plunging it in two or three times. This process will take but a minute or so. Now dip it into the second kettle with water at 134° or 135°; keep the Wheat well stirred. Perhaps there is no better way than to lift it out and plunge it in several times. This should be continued ten or fifteen minutes, according to the temperature of the water, and then spread out to dry. A second person should regulate the temperature of the water and do nothing else. Probably it will be found best to have a fire under kettle No. 2, sufficient to raise the water to 145° or 150° Fahr., and then add cold water to reduce it to 134° or 135° Fahr., when the seed is put in. If at the end of ten minutes the temperature of the water has not been reduced below 133°, the seed should be removed, and dipped into cold water. If below 133° F. it should be left in fifteen minutes, or even longer if the temperature should fall below 130° Fahr. The treatment is essentially the same for Oats, except that the temperature of the water in kettle No. 2 should be 139° or 140° Fahr. when the Oats are put in." The importance of taking some such precautions as the above against the spread of smut will be realised by reading the following summary relative to it, and to its effects in Michigan:—

1. The loss to Michigan this year in the Oat crop alone, caused by smut, will exceed 1,000,000 dols., and this is a low estimate.
2. The smut of Oats, and the stinking smut of Wheat, are parasitic plants.
3. The spores of these smuts attach themselves to the kernels of Oats or Wheat, and are sown with them.
4. The spores germinate at about the same time the seed germinates, and in some way enter the young plant and live upon it until, finally, the head of smut appears.
5. Both of these smuts can be entirely treated at a slight expense by the Jensen or hot-water treatment.
6. For Wheat, the temperature of the water in kettle No. 2 should be 134° or 135° when the seed is put in. The seed should be taken out in ten minutes if the temperature does not fall below 133° F.; and if below 133°, it should be left in fifteen minutes, or even a little longer if the temperature should fall below 130°.
7. For Oats, the temperature of the water should be 139° or 140° when the Oats are put in, and they should be taken out in ten minutes if the temperature

is not below 135°. If below 135° F. at the end of ten minutes, they should be left in fifteen minutes, unless the temperature falls below 130° F., when they should be left in a little longer. During treatment, see that the temperature of the water in kettle No. 2 does not rise above 135° for Wheat, and 140° for Oats.

8. Professors JENSEN, SWINGLE, KELLEMAN, ARTHUR and others have found that this treatment not only removes the smut from the crop, but improves the growth and increases the yield.

9. The increased yield is sufficient to pay for the labour and trouble of treatment several times over.

10. Do not conclude that you have no smut because you did not see it. In the case of Oats, the smut is mostly blown off before harvest, and the smutted stalks, being shorter than the healthy ones, are not observed.

WILLIAM R. SMITH.—The *American Florist* gives an excellent portrait of President-elect W. R. SMITH, of the Society of American Florists:—"Mr. SMITH was born in Scotland in 1828, and served as an apprentice at Lord ELCHO's. He then served as journeyman and foreman for three years in famous gardens of sundry noblemen, serving one year in each place. He was then admitted to Kew, where he served the usual two years. While there he met Professor ASA GRAY, and formed a friendship with that grandest of botanists, which lasted until the Professor's death. He landed in Philadelphia, served for a few weeks at Mr. DUNDAS', then a famous place, and was then sent by Mr. ROBERT BUIST to a swamp in the city of Washington, with three small greenhouses, which was there, and had been called the Botanic Garden on the map only. It contained the rare plants collected by the Wilkes exploring expedition; but that was about all, and it was certainly in a very crude condition. Mr. W. D. BRECKENRIDGE then had it in charge. The death of Mr. DOWNING promoted Mr. BRECKENRIDGE to the position of landscape gardener of the public grounds. Mr. SMITH was placed in charge of the greenhouse, under Mr. BRECKENRIDGE for the first year. Mr. BRECKENRIDGE, who still lives, had been around the world with Captain WILKES, and had collected many rare and valuable plants. He is the author of a valuable book on Ferns. The following year a special appropriation was made for the garden, and Mr. SMITH was appointed its superintendent in 1854, which position he has held ever since. The growth of the Botanic Garden, its importance to the country in furnishing rare trees and plants to every section, in determining by practical experiment the species most suited to different climates, and in making known those that are most desirable for shade trees in the cities, are strong testimonials to his industry and devotion to his work."

PLANT PORTRAITS.

DIFFENBACHIA MELEAGRIS.—An Aroid from equatorial South America, with green leaf-stalks, spotted with white; lanceolate leaf-blades, deep green, with a few spots. *Illustration Horticole*, t. 159.

LABISIA SMARAGDINA.—A stemless Myrsinad. Leaves oblong, obovate, dark green. Flowers small, pink, numerous in much-branched panicles. It was exhibited at the Temple Show in May last. *Illustration Horticole*, t. 160.

BELGIAN NOTES.

WE learn with pleasure, which many horticulturists will share, that M. Fréd. Burvenich père, Professeur de l'Ecole d'Horticulture de l'Etat, of Ghent, and author of several horticultural books, has been made "Chevalier du Mérite Agricole de France," at the same time with MM. Rodigas and Ad. Vandenheede, of Lille.

Polygonum orientale fol. var., commonly called Persicaire du Levant, is not only an excellent bee plant, but very ornamental in habit and in foliage, which is green and yellow. It is exceedingly effective grown singly on lawns, and is increased by seed.

Magnolia grandiflora Gallisoniensis.—This noteworthy variety of *M. grandiflora* is largely grown at Angers for the Paris markets, where it is sold as a decorative plant for halls, court-yards, &c. At Angers there are boulevards planted with this *Magnolia*, which does especially well in the maritime climate of Nantes. In the squares of Angers, the plant is alternated with *Eriobotrya*, *Lanrustium*, *Elaeagnus argentea*, &c. In Belgium it is almost unknown, except in greenhouses, where it blooms well. The flower is very large, cream-coloured, and suggests that of a white Water Lily. In the centre of this pure, cold-looking blossom, the stamens and pistil rise in a cone. The scent is peculiar, and agreeable; the foliage is bright, shining green, and very ornamental—altogether an excellent plant for greenhouse or conservatory.

New Sonerilas.—La Société Horticole, Louis Van Houtte père, has lately obtained through the skill of one of its foremen, M. Marchand, three excellent hybrid *Sonerilas*, remarkable for the unusual size of the foliage. These three hybrids are:—

1. *Sonerila Souvenir de Madame Van Houtte*.—Foliage like that of a *Bertolonia*; the adult leaves are about 6 inches long by 3 broad; they are deep blackish-green, spotted with greenish-white, with a polished appearance. From each little spot springs a hair, and the general effect is thus very peculiar; the edges of the leaves bear short hairs at regular distances. The petiole and mid-rib are claret-coloured, the veins very distinct. The female parent of this hybrid is *S. Hiba*, the male a newly-introduced species. It appears to be easier to cultivate than other known *Sonerilas*, and is sturdy in growth.

2. *S. Léopold II*.—Leaves narrower, but a quarter of an inch longer than those of the last-described species. The foliage also is darker than that of the above, the spots about the same colour, but larger. A hybrid from the same parents.

3. *S. Marchandi* ×.—Foliage nearly black, leaves smaller than those of the two preceding varieties, the spots less numerous, but with pinkish tint on the edges and tips of the leaves.

Some new hybrid Bertolonias.—At the above-named establishment there are some new *Bertolonias* from *B. Van Houttei* × *B. roseo-punctatissima*. M. F. Marchand has produced the greater part of the varieties sent out by M. A. Bleu, so that no doubt the two hybridisers operated in the same manner on the same species, and we have chosen for notice about a dozen of the best among the many new varieties. The hybrids are not yet named, so we will distinguish each by a number.

1. A variety resembling *B. Madame la Baronne A. de Rothschild*, but will be of greater height, the colour brighter, a peculiar shade of pink, well set off by the bronze-green background; these handsome leaves are longer and broader than those of *M. Bleu's* variety.

2. An excellent variety of the habit of *B. Van Houttei*, and the same markings, but in pink; the foliage large, the veins bright silvery-white at base, shading into pink; the tip of the leaf is quite pink.

3. A hybrid with pink veins deeper than those of the other varieties, the leaves longer.

4. Is quite similar in every respect to *B. Madame Alp. Bleu*.

5. A dwarf variety, with leaves 7 by 4 inches, of a bright green colour, speckled with pink, resembling *B. albo-punctatissima*; the habit is that of *B. Van Houttei*. The young leaves are coppery-red, the older ones retain a border of the same colour, and the adult leaves have but a tinge of it, which is accentuated on the margin.

6. Foliage dull green, nerves white, spots pink, in the large leaves the green predominates; habit good.

7. Another good variety, with large foliage so shaded as to appear "shot;" ground-colour velvety black-green, mid-rib bright silver, veins pinkish-white or pink, spots bright pink.

8. A plant of capital habit, leaves very large, elliptical; mid-rib wide and undulating, bright pink. The very large spots are of the same colour.

9. *J. C. Stogdon*, dwarf, large-leaved variety; in

each part of the leaf, which is bounded by the principal veins, there are innumerable specks of bright pink, which are very effective against the bronze-green background.

10. Belongs to the category of *B. roseo-punctatissima*; leaves large, deep green, with clear green veins, and a pretty metallic lustre over them, the spots less numerous, but of a very delicate pink.

11. A more uniformly-coloured hybrid than are the others. Bright carmine, as is No. 1.

12. A variety with leaves 6½ by 4 inches; the base and half the blade pink against a green ground; the top green, with veins and spots of white. *Ch. de B.*

THE APIARY.

FEEDING UP.

THERE should not be any further delay in giving stocks their full complement of food for the winter. All hives short of 20 lb. of stores should have sufficient syrup given them to make up this weight, which will last them well into next April. The syrup should be made by boiling for a few minutes 5 lb. of the best granulated or lump sugar to one quart of water, and given to the bees warm. A rapid feeder that will hold 20 lb. of syrup if necessary, is the right kind to use, although a glass pickle-bottle covered with muslin and inverted over a piece of perforated zinc, answers the purpose.

Winter Passages.—Winter passages of some kind or other are a necessity for successful wintering, and should on no account be overlooked. Two pieces of stick, each about half an inch thick, laid at right angles over the frames, and then covered with the quilt, is a rough-and-ready way of providing them. A piece of thick bamboo cut in halves, answers much better. If the latter is not procurable, it does not take long to make passage-ways by taking a piece of deal 2 inches wide, and three-quarters of an inch thick, and scooping out the under-side with a half-round chisel. If the top edges are nicely rounded off, the quilt fits down close, and makes it a better job. They should be about a foot in length.

Antiseptic Quilts.—Attention has lately been drawn to the use of antiseptic quilts as a prevention to the diseases to which bees are subject, and in districts where foul brood is known to exist it certainly would be worth the while of beekeepers to try them. The material used is a kind of tar-felt, commercially known as "Latus" felt, and it can be obtained from some of the dealers in appliances.

Entrances.—Entrances that have been narrowed to prevent the inroads of wasps and robber-bees, should soon be opened to about 6 inches where American-cloth is used next the frames, for unless sufficient ventilation is provided, the moisture condenses inside, often causing dysentery, and the combs to become mildewed and rotten. An eke, or raiser, put under hives, is a good plan, so as to make the bottoms of the frames stand 3 inches or so above the floor-board, as this insures perfect ventilation, and prevents any possibility of the entrances getting blocked in the winter with dead bees. *Expert.*

THE HERBACEOUS BORDER.

RUDBECKIA SPECIOSA.

IN the herbaceous border, this Composite is making a brilliant show. We find that the cut blooms are excellent for filling vases and flower-glasses, being both pleasing to the eye, and lasting. As is well-known, the disc is of a blackish-purple shade of colour, and the florets of a deep orange. The plant, which grows to a height of 2 feet, is easily increased by divisions, and being very hardy, good clumps may be obtained in a short time by planting in good well-drained soil. Where there is much flower-bedding, this species might be used for the middle part of large beds; and besides remaining from year to year, its use would render the propagation of tender plants unnecessary in some measure. *H. M.*

HOME CORRESPONDENCE.

CALADIUMS.—To winter these Aroids well, and without experiencing any loss through rot, great care should be taken that the plants are not left too long in the cooler houses, where they may have for sometime been used as decorative objects, this being a fertile cause of the tubers wintering badly. If these are not exposed in a moist state to a low temperature, but gradually dried off in a warm one, and stored in sand in a warm dry place, 55° to 60°, almost every tuber will keep sound. *H. Markham.*

WEIGELA ROSEA AS A WALL PLANT.—It may not be generally known that this shrub makes a capital wall plant. I saw it growing at the foot of a cottage wall with a western exposure, and a great success it was, literally smothered with its rosy-pink flowers. This *Caprifolioid* is by the cottagers in the neighbourhood known as the Apple-blossom plant. In this case great pains had been taken with the plant in question in neatly keeping the shoots tied in pretty close, therefore, it was truly a neat wall plant. No doubt the warmth derived from the wall assisted in its flowering so finely. *E.*

HELIOTROPE SWANLEY GIANT.—This is unquestionably the best of the *Heliotrope* genus for bedding use, and is not nearly enough employed in the flower garden. Under good cultivation the plants grow 2 feet 6 inches high, even when they are but small when planted. The flower trusses often measure 10 inches across, while the colour and perfume leave little to be desired. Now is a good time to take cuttings of the short side-growths which have not flowered, wherewith to provide stock for next year's display. If these are inserted to the number of six in a 3½-inch pot, and afforded a slight bottom-heat, they quickly make root; they are best wintered in the same pots without disturbing them. *Heliotrope*s to be effective out-of-doors need to be planted in bold masses, this is a point not to be lost sight of in taking the cuttings. *H. M.*

TWO FINE MULBERRY TREES.—A few days ago, when looking through Trafalgar Park Gardens, Earl Nelson's beautiful place near Salisbury, my attention was drawn to a remarkably fine specimen of the black Mulberry growing in one of the kitchen gardens, and within 15 feet north of a high wall. The trunk is straight for about 5 feet from the ground, and has a circumference of 5½ feet; the head of branches is of good size, healthy, and well cropped with good-sized fruit. The situation of the gardens at Trafalgar is very high—I should say, as high as the spire of Salisbury Cathedral. The soil is a light loam, of an average depth of about 18 inches. Another Mulberry tree, which is more remarkable for its healthy, vigorous, and fruitful condition and symmetrical outline than for its great size, is growing in Dr. W. D. Wilkes' bijou garden, The Canal, Salisbury. This tree stands in the centre of a well-kept lawn, which towards the end of August is strewn with fruit of the Mulberry, which, for size, colour, and flavour, excel any hitherto seen or tasted by the writer. *H. W. W.*

HARRISON'S MUSK.—This is one of the best of summer bedding plants it is possible to employ. The growth is free, yet neat, and always covered with bloom, while the perfume is delightful, especially when associated with *Heliotrope*, as it is here; planted in a large mass as a carpet to this, dotted here and there in the same bed are plants of a dark-coloured *Ricinus cambridgensis*, and some well-coloured examples of *Zea gracillima*. The best way to preserve a stock of this Musk through the winter is to dig it up from the beds in flakes, plant it in boxes of sandy soil, and winter in a cool house or frame free from frost, and keep the Musk neither in too wet nor too dry a state, but just in a happy medium. By dividing the roots in the spring, a quantity of plants can easily be raised for another season. *M.*

TUBEROUS BEGONIAS AND SUB-TROPICAL PLANTS.—With a view to relieve the somewhat flat and formal appearance of some beds planted with tuberous Begonias, some subtropical plants were introduced, such as *Ricinus Gibboni*, *Abutilon Thomsonianum variegatum*, variegated Japanese Maize, the blue Gum Tree, and *Meliantbus major*, with satisfactory results. These plants were put out at a distance apart, which prevented their spoiling the effect of the Begonias by crowding; each being

a specimen in itself, all harmonised with the Begonias below them. Independently of the good effect brought out by subtropicals, the shade which they afford the Begonias acts beneficially in bright weather, and when the flowers of Begonias become smaller, if the beds are not kept moist, which in many gardens is not possible. In connection with tuberous Begonias as bedding plants, the employment of hardy plants of low growth has again been a success. This season I planted *Sedum lydium*, the deep green colour of this plant making quite an agreeable contrast to the varied colours of the flowers above, as well as with the subtropical subjects. As a conservator of moisture in the soil, the *Sedum* has been very useful this dry season. E. M.

EUCALYPTUS GLOBULUS, 110 FT. HIGH.—The large tree here shown in the photograph is *Eucalyptus globulus*. It was somewhat difficult to get a good plate of it, owing to the large size of the plants near it. The plants showing in the front at the bottom of the picture are scarlet *Rhododendrons*, varying from 20 to 40 feet in height, and directly underneath the *Eucalyptus* is a nice plant of *Phyllocladus rhomboidea*, about 15 feet in height. The Conifer showing on the left-hand side of the *Eucalyptus* on the top of a large boulder of rock is *Cupressus macrocarpa*, a tree about 30 feet high, and to the left of that is a tree of *Eucalyptus resinifera*, 35 feet in height. The tree, showing on a rising ground to the right-hand side of the *Eucalyptus* is *Acacia decurrens*, about 20 feet high. These facts are mentioned so as to give a correct idea of the size of the specimen tree *Eucalyptus globulus* here shown. The tree was planted by the present proprietor in the spring of the year 1862, so that it is about thirty years old; the height of the tree is about 110 feet, and it has a girth at the base of the trunk of 10 feet 3 inches. It is growing in a warm but very dry situation on a solid foundation of conglomerate rock, and with very little soil, consequently it does not grow so fast as it would do on a very rich soil of great depth. This, no doubt, has enabled the tree to withstand the effects of severe frosts, making slow growth, but thoroughly well-ripened wood. It has steadily increased in size and firmness up to its present dimensions. It flowers very freely, and bears a great quantity of seed which germinates very well, plants having been raised from it several times. The photograph is by Mr. G. M. Jeune. *T. Sharman, Rozel Bay, Jersey.* [With this came an excellent photograph, which, considering that similar trees have been figured previously, though none so large as this, we do not reproduce. We thank our correspondent for its transmission. Ed.]

WATERING WALL FRUIT TREES IN AUTUMN.—Very few gardeners give their wall fruit trees sufficient water at the roots in the autumn months, for after the crop is gathered, Peaches, Plums, or Cherries are considered to want nothing for a time. Take, for instance, the present season here in South Hants, we have had this year but 12.50 rain up to the present time (September 14), which is much below the average rainfall. During the last month 3 inches of rain fell, but the greater part came from one direction only—south-west—which, of course, prevented fruit trees growing against an east wall receiving either their share or sufficient to thoroughly saturate the soil near the wall, and it is surprising what a quantity of moisture a brick-wall alone will absorb. The overhanging coping on the tops of walls, so useful in the spring when the trees are in bloom, prevent to some extent rain falling close to the wall when it comes from the opposite side, and so do the leaves. Now, if the soil about the roots of one part of a tree is not in a sufficiently moist state, how can the tree be expected to produce stout fruit-buds? It gets really prematurely ripened, and wood and buds are therefore in an immature state. If the weather be very dry after the fruit is gathered from our Peach trees, we give the soil near to the wall at least two thorough drenchings with water before the leaf falls, and Plums one good soaking of water, and this immediately the fruit is all gathered off the tree. Peach trees growing in different aspects out-of-doors seldom get enough rain or snow, or we should see better examples of Peach growing oftener than we do. I look upon the Peach crop as the most certain of all hardy fruit. If the trees are in the right condition there appears to be no reason why we should miss a crop of fruit at all in any year; and now that the number of varieties has so increased,

ripe fruit can be had for nearly three months out-of-doors, which is a considerable advance on former conditions. For such a return as this, it is but little to devote some spare hours to supplying moisture to the roots at a time when some persons suppose that it is not wanted. S.

ROSES IN BRITISH GUIANA.—May I ask some of your readers to help me to get information on the following point? For some years past, I have tried to grow Roses in my garden in tropical America—in British Guiana; and though I have succeeded with certain kinds, I have never succeeded in finding any dark red Roses which will succeed in those parts. Probably some of your readers, with considerable experience of forcing Roses, might be able and willing to give me a hint, especially if guided by information as to the kinds which succeed in Guiana. And as there must be many of your readers who are interested in tropical gardening, any information which you may be able to give on this point will be of interest to others besides myself. Tea Roses naturally do best with us—the more double ones, such as *President*, better than the more single kinds, such as *Madame Falcot*. Some of the descendants of *Gloire de Dijon* do admirably—notably the comparatively new *Roses Kaiser Friedrich* and *Kaiserin Friederich*. But the best of all Roses with us is the old favourite *Maréchal Niel*. The next best to that is *La France*, which is an almost perfect Rose for the tropics, there retaining not only its colour and form, but also, as very few do, its perfume. I shall be greatly obliged if any one will give me any hints which will lead me to any good red Roses, especially dark red Roses, which will stand heat. I think, too, that both to me and others any hints as to the exact best time and method to be observed in transporting Roses long distances to the tropics might be valuable. *Everard F. von Thurn.*

DELPHINIUMS—These have been so improved or late years that they are now about the finest and most showy plants one can have in the garden, the most suitable place for the tallest varieties being in the foreground of shrubs, or at the back of wide borders, where their fine spikes of flowers are very effective. Some of these tower up to a height of 12 feet, and branch freely out, giving flowers of great size, and of various hues, as they run through nearly all the shades of blue; some are double, but the single ones are the best. Among the older kinds my favourites are: *D. formosum*, which has been out many years, and will take a good deal of beating; and another, named *Bella Donna*, is a very fine thing. This latter is a lovely pale blue, and is a very shy-seeding variety; but most others are only too free in that respect, and should, if not wanted for sowing, be relieved of them, as they weaken the plant, and prevent late flowering. The seeds being ripe now, anyone who would have Delphiniums should get a packet from those who make a specialty of the plants, and sow at once, as by doing so the plants will be strong enough to blossom next year. A good way of treating them is to prepare a spot on a warm sunny border, by putting an inch or two of fresh fine rich soil, and sow on that, just covering the seed, and pressing the soil down firm and smooth, when, if a handlight is placed over, and kept closed, the seed will quickly germinate. They should be planted out in the spring to the positions where they are to flower. The ground should be prepared for them by being deeply dug, and having a good dressing of rotted manure worked in. I generally plant in threes, and afterwards pull out or destroy the two that are inferior, and leave the best to stand permanently, if deserving of space. Those who would have named kinds may get them now, or wait till spring; but if obtained at once in pots, they will be all the stronger. Delphiniums increase readily by division of the crowns, and the best time for doing this is just when the plants start to grow, when they may be safely taken up, cut through, or pulled apart, into as many pieces as the crown buds will allow. J. S.

LAPAGERIAS.—The *Lapagerias* here (Nash Court, Faversham), are now, though a little past their best, worth travelling many miles to see, it being a sight I venture to say, is seldom met with. *Geo. Humphrey.* [The Nash Court variety of *Lapageria rosea* is one of the finest, and it has been noticed in these pages, January 14, 1888. It has larger leaves and flowers than the ordinary form of *L. rosea*. Ed.]

THE NATIONAL ROSE SOCIETY.—Was it not Canning who said that nothing was so fallacious as facts, except figures; and when we find rival Chan-

cellors of the Exchequer taking an entirely different view of the same figures, it is hopeless for meaner mortals to do better. However, let me say this, in answer to Mr. Grahame, that the tables were neither made by me, or for me; they were drawn up by a gentleman who has never exhibited a Rose in his life, and who had no personal interest in the matter whatever. Understanding that he had done so, and knowing from long experience how accurate he was, I asked him to let me have it; this he courteously did, and *pace*, Mr. Grahame, I have so much confidence in his accuracy, that I decline to alter my statements. Mr. Grahame is satisfied, and so am I, "which makes it very nice for all parties." *Wild Rose.*

A KNOTTY QUESTION.—The letter I give below from the *Scotsman* touches a point which must have occurred to many of your readers. In many gentlemen's gardens, it is a well-known fact that they can only be kept up by the selling of the produce. But many gentlemen only sell their surplus fruit, and thus bring down the price of the grower for the market. But how these latter individuals, and those who are well off who sell their fruit, could be taxed in any way would be difficult to determine. It is a great blessing, again, that the price of good fruit, like Grapes and Peaches, is oftentimes within the reach of people of moderate means. *Fagabond.*

September 17, 1892.
Sir,—Your issue of yesterday contained a report of a recent Haddingtonshire Court of Appeals against over-assessments. One of the cases has more than a local and passing interest. The appellant, a market gardener, stated that he had laid out above £2000 on his glasshouses, and that he was taxed on their value. Although the Court remitted in full the amount of this tax, the nature of his complaint was not that it was in itself either exorbitant or illegal. He simply stated that erections of a similar, but more extensive character, were owned and worked by many of the leading proprietors in this county, and that, while the fruit, &c., raised in them was regularly sold, thereby lowering the price of his own produce, these erections were totally untaxed. This, he justly remarked, placed him at an unfair disadvantage in the open fruit market.

East Lothian may not be the only county in Britain where a similar system prevails. It is to be hoped that the moral courage shown by Mr. Robert Macfarlane of East Linton in exposing its unfairness, and also the consequent loss of revenue, may tend to an equality of assessments against all fruit-ers being shown in future rolls.—I am, &c.,
TAXPAYER.

"SUCCESS" PEA—Referring to the discussion going on in the *Gardeners' Chronicle* in reference to this Pea, I shall be glad to be informed wherein it differs from *Holmes' St. Duthus*, which was certificated by the Royal Horticultural Society in August, 1887, and sent out by Messrs. Hurst & Sons in the autumn of that year. The *Gardeners' Chronicle* of September 4, 1886, describes it as follows:—"St. Duthus Pea—of which a plant was sent bearing forty-five pods, with about 360 Peas in all, an average which can scarcely be excelled. Seed large, colour deep green, sweet in flavour." Messrs. Hurst & Son described it as a "late wrinkled variety, of a robust habit, and should be sown very thin. Height, 3½ feet." Success was first catalogued by Messrs. Veitch & Sons in 1889-90, and their description of it tallies generally with that of Messrs. Hurst & Sons and the *Gardeners' Chronicle*, but they make it to be 4 feet in height. They did not issue it with a raiser's name attached to it, nor did they claim it as their own production. I think there can be no doubt the Peas are one and the same, and if so, then it would appear that the Royal Horticultural Society has given two certificates to the same variety under different names. *Enquirer.*

ORCHID GROWING MADE EASY.—No one who has had the good fortune to have seen Mr. Crispin's Orchids at Fishponds, near Bristol, could fail to have been struck with the easy, effectual, manner in which a collection of nearly one thousand plants is grown. There are fine Orchid-houses, and all culture-worthy species and varieties are represented. Good *Odontoglossums*, fine specimen *Cattleyas*, large masses of *Oncidiums*, new and rare hybrid *Cypripediums*, of which there is a good collection; *Dendrobis* in variety new and old, such as *fimbriatum*, *Phalaenopsis*, *Statterianum*, and *superbians*; several fine specimens of *Cattleya Warocqueana*, full of sheaths. All of these afford evidence of the excellence of the system of cultivation in vogue at Fishponds. It may sound perhaps rather strange to some that a lad of fifteen only is kept on this place, and his work is mainly to attend to the fires and to do a little occasional sponging of the foliage of the Orchids. Watering is attended to about once or twice a week by Mr. Crispin himself, and all goes merrily. Mr. Crispin's methods must be admitted to

be economic and effective, and very simple. By some engineering contrivance the atmosphere can be charged with vapour to any degree as far as dew-point, but it is usually kept at about 5° above the dew-point, this affording a comfortable atmosphere, especially for plants which are growing; and the volume of vapour can be reduced or increased by merely turning a valve, so that a houseful of plants may be dried off or ripened, or started into growth, as may be desired. I have an idea that Orchid growers, if they tried Mr. Crispin's plan, would soon take a great fancy to the contrivance, as for instance there is no throwing water about the stages or floors, and the syringe is not required, therefore a great deal of the dirt deposit which remains on the foliage after the water has evaporated is avoided, and the plants are thus kept clean, a point always sought after by good gardeners. In winter, I think this automatic system of damping down is a great boon. When say, in cold weather, there are from 10° to 20° of frost urging us to put on more coal, and then there is a difficulty in keeping pace with the dryness of the air in the house, due to the heat of the hotwater

was the position of the respective committees in relation to subjects grown at Chiswick for trial, and to which they are occasionally called upon to make awards of merit. Until the present year, the granting of three marks to any subject was followed, so I understood, by the giving of certificates to the persons sending subjects there, so honoured. This year's schedule, however, shows a newly-introduced condition made by the council, which renders it needful, when practicable, that examples of the subjects honoured should be presented at a regular meeting of the committee at the Drill Hall for confirmation of the award, and the granting of certificates. The present position of things was first brought to the notice of the fruit committee at the meeting held at the Drill Hall on September 6, when Mr. Wythes presented for a certificate a dish of Veitch's Success Pea. It was at once stated that this Pea had been certificated at a special meeting held at Chiswick a few weeks earlier. Of course, Mr. Wythes was absent from the table when this matter cropped up, and it gave rise to a long discussion as to who, under the new regulations, was entitled to

be some rule made as to the numbers of the committee forming a quorum, and when a full quorum failed to attend at Chiswick, then the awards should be subject to the sanction of a full meeting. I entirely fail to see what bearing the question of the certificate granted to Figs grown at Chiswick has upon the one under discussion. If these Figs were purchased by the council, and grown at Chiswick for purposes of profit, as presumably they are, who were better entitled to the certificates than the growers? If they were sent by the continental raisers for trial, they were entirely satisfied that certificates were awarded. The case is not at all analogous to the one under discussion. The suggestion that gardeners find it more difficult to obtain certificates than do members of the trade, is absolute baseless. Take the case of Mr. Myles' new Grapes, and Mr. Allan's new Strawberries, for instance; but these were really meritorious subjects, whilst some which came to the table from presumably eminent gardeners, elicit only surprise, and not admiration. Then there is a suggestion that no person interested in any subject grown at Chiswick should be on

FIG. 66.—GREAT BANYAN TREE IN THE BOTANIC GARDEN, CALCUTTA, (SEE P. 399.)

pipes, when moisture is quickly dried up, and the work of damping down is never finished. At night it is even worse; a careful man looks round at ten or eleven o'clock, and damps the benches and tables and floors, and often very cold water comes into contact with warm pots which is not beneficial to the plants, and doubtless causes a check in some cases. The gardener then goes to bed, and seven or eight hours intervene ere the plants are again looked at. In this interval the house has become thoroughly dry, with the consequence that young growths are little by little weakened, and plants are lost. This is not all, for drought is highly favourable to the increase of insects, such as woodlice, cockroaches, and thrips, and Mr. Crispin's contrivance renders this kind of plague of the Orchid grower less irksome. *P. W.*

CURIOS FREAK OF A CLEMATIS.—In the dining-room of a house I was staying in lately, a Clematis Jackmanni branch had come in through the ventilator, produced four flowers, and, under the influence of heliotropism, made vigorous growth for the window. It would be interesting to hear other instances of this. *Vagabond.*

CERTIFICATES OF THE ROYAL HORTICULTURAL SOCIETY.—Setting aside personal matters with which I have nothing to do, what I did discuss

the certificate to the Pea, which every member of the committee was anxious to grant. Of course, had not the Pea been previously grown at Chiswick, and there received three marks, it would not have had a certificate granted, consequently it was held by most of the committee that as the Pea derived its honours from its good qualities shown at Chiswick, the person sending it to Chiswick for trial on the invitation of the council, as made yearly, was the proper person to receive the certificate. When it was said by the estimable chairman, "We grant the certificate to the Pea," it was unanimously agreed that such certificate should be granted; but, after all, this incident, trifling as it may be, forms an admirable basis on which to raise a discussion, were it needed, as to what shall ultimately be the position or power of the committees in relation to awards at Chiswick. Whilst most desirous of working in complete harmony with the council, the members think that, with even greater facilities before them at Chiswick, to discern the merits or otherwise of subjects than they can have at the Drill Hall—the same power to grant certificates should exist in one place as in the other. [Only after comparative observation throughout the whole season. Ed.] That, of course, would ensure that the person sending the subject for trial at Chiswick received the certificate. I think, however, there should

any sub-committee. Well, no sub-committee has yet been appointed, and if any is, it will be time enough to raise that question. If anyone has taken notes at Chiswick, or even at the Drill Hall, of subjects in which they were directly interested, it would be as well to specify cases, and mention names. How does the matter stand, for instance, when, say the Duke of Northumberland sends from Albury subjects for award to the fruit committee, and his gardener at Syon sits and adjudicates, or *vice versa*, at the floral committee table. That, of course, opens up a very interesting matter, and shows that there are always two sides to a question. However, there can be no doubt but that some good will come out of this discussion, which I have raised in a very temperate way. The matter has, of course, attracted the attention of the council, and we may look for a solution in due time. P.S.—The fruit committee consists of gardeners 19, seedsmen and nurserymen 11; others, chiefly amateur or unattached 10; total, 40. *Correspondent.* [It is clear that the Chiswick Certificate is a much more valuable testimonial than the ordinary First-class Certificate, and means should be taken to emphasise the fact. Ed.]

VICTORIA REGIA.—The Victoria has been very fine, and flowering freely. The first flower opened

in May. This is the second year on the same plant. Our Nymphæas have also flowered freely, producing very large flowers. *J. P., Cherkeley Court.*

LILIES REMAINING DORMANT.—This year an unusually large proportion of the Lilies in my garden, I think certainly more than half, have failed to make any growth above ground. I find them apparently quite healthy and sound, when digging and transplanting herbaceous plants. The kinds which most often remain without coming up are *L. colchicum*, *L. testaceum*, *L. candidum*; but they appear to grow larger during their stay underground. Another peculiarity of Lilies is the great irregularity with which they make their first appearance above-ground after germination from seed. I scatter seed of some kinds, especially *L. colchicum*, freely about the flower beds. In some places the young plants appear in a year; in others, sown at the same time, the bulbs grow underground for two years or more before making any show above ground, and I am almost certain that flowering stalks of *L. colchicum* are in some cases the first indication that a bulb has matured on the spot from seed. *C. Wolley Dod, Edge Hall.*

SCOTLAND.

NORTH OF SCOTLAND HORTICULTURAL AND ARBORICULTURAL ASSOCIATION.

The members of this association held their annual meeting in Aberdeen on Wednesday evening, September 22, Mr. C. S. France, President, in the chair. The secretary's and treasurer's reports were read and adopted. From the accounts, it appeared that there was a balance to the credit of the association of £17 16s. 10½d. The following gentlemen were appointed office-bearers for the ensuing year: President, Mr. C. S. France; Vice-president, Mr. G. Ross, Cranford; Joint-secretaries, Mr. W. Reid, Hadden Street, and Mr. J. Minty, Canal Road, Aberdeen; Treasurer, Mr. Wyllie. A motion anent alterations of rules 1, 3, and 5 of the constitution of the association was then brought forward. Regarding rule 1, the name of the association was altered to the "North of Scotland Horticultural and Arboricultural Association." To rule 3 the following addendum was made: "Amongst means for extending the objects of the association we are to grant awards for essays on, and for collections of native herbaria and woods." Rule 5 was altered to admit apprentices at a subscription of 1s. per annum. Three silver medals were offered as awards for the subjects mentioned above, a maximum sum of £3 3s. being voted for the purpose. The usual votes of thanks terminated the proceedings.

FROST IN SCOTLAND.

Writing under date of Saturday, September 24, our Aberdeen correspondent states, that on the morning of Tuesday, September 20, and three following days, sharp frost prevailed in the North of Scotland. Reports from various districts are to the effect that much damage has been done to vegetation. The Potato tops over a wide area have been blackened, and it is to be feared the crop has been seriously injured. Away in the uplands about Braemar, the weather experienced during the past few days has been more like midwinter rather than in the month of September. At Castleton Observatory (Braemar), 10° of frost were experienced in the shade; and the self-registering thermometer on the grass indicated 17° of frost. On Wednesday and Thursday the night-frosts were followed by splendid sunshine, the heat being almost oppressive. The barometer is both high and steady.

TAYSIDE, PERTH.

Among the numerous suburban residences along the banks of the River Tay, the seat of R. Pullar, Esq., holds a conspicuous position, nestling snugly among trees on a beautifully-kept lawn, running close to the river, and, like most of such suburban homes belonging to proprietors like Mr. Pullar, who are imbued with refined taste, and are in affluent circumstances, horticulture in due time is well represented in such favourable positions. We had only a

very short time to pass quickly through this place, after a special effort we made, to see the fine conservatory at Tayside, which is attached to the spacious mansion. It is a very elaborate structure, in which one can have bodily exercise and enjoyment in fresh air, among flowers, to one's heart's content. The length is about 132 feet, and over 30 feet wide. The roof being lofty and well clothed with climbing plants, healthy enjoyment can be at all times obtainable, and when the stages or floors of such houses, as the one indicated, are not crowded with plants—leaving free open space—the pleasure in them is greatly increased, when a promenade from the drawing-room to the conservatory, thence to the other plant and fruit structures. As at Tayside, convenience and economy are combined. The vegetable garden and other less ornamental parts are well obscured from the general view when one is in the ornamental grounds. The plants in the conservatory are mostly of the usual decorative species—gay to be sure, but among great numbers of Begonias, Pelargoniums, Achimenes, Carnations, Lilliums, white Petunias, baskets of white Lobelias, &c., plenty of Palms, Ferns, Dracænas, and other greenery modified the whole to give a very pleasing effect; fine Camellias in the centre (if not of a class so popular as they once were), give a pleasing effect to this gay structure which may well meet the desires of the most fastidious. The stages all round the sides of the house are low, giving full facility to workmen while manipulating; and when one looks down upon plants instead of up to them, their beauty is much enhanced.

Passing from this conservatory, a small house is entered, in which are a good selection of Gloxinias; interspersed among them are Ferns, Cycads, and Palms. Two vinerias are filled with excellent Grapes of their classes—Madresfield Court, Alicante, Lady Downes (among the finest examples we have seen for some years), Gros Colmar, Muscat, and others, all well done. In a corridor is a pleasing arrangement of white and scarlet Lapagerias, Habrothamnus splendens, Abutilons, and other plants drooping from the roof. A house of remarkably fine Begonias is worthy of note.

In a small structure are capitally grown *Calanthe Veitchii*, growing along with Poinsettias, Dracænas, &c. A piece of rockery is passed, almost covered with Ivy, in which is a pleasing arrangement of Ferns, growing among ornamental stones, with water trickling past them. The Melon-house is passed through, in which were growing plenty of fruit large in size of Monroe's Little Heath, a variety which is very hardy, resists disease well, sets freely, and the fruit can be had of serviceable size by allowing, say, half-a-dozen, to each plant. In a Peach-house about 80 feet long, Rivers' Early Silver Peach was a fine crop; Stirling Castle is another which is valued for hardiness and free cropping. Lord Napier Nectarine is much valued, and fruits freely at Tayside; so also does Pine-apple Nectarine. In the house indicated, 13° of frost were registered while the trees were in flower. In such structures it is of great moment to have at all times heating power to resist frost, and to help late-fruited sorts. Warmth from hotwater pipes, when late fruits are ripening, with air and other requirement skilfully applied, do much to render Peaches, Nectarines, and other stone fruits worthy of cultivation; while others that may colour and appear pleasing to the eye (when ripened during dull weather), are only of service in the culinary department, and we have seen some kinds of little value even there. We left this charming seat after a pleasant half-hour spent with Mr. Pullar's intelligent and very kind gardener, Mr. McDonald. *M. T.*

SOCIETIES.

CHELTENHAM HORTICULTURAL.

SEPTEMBER 21, 22.—The annual autumn show of the above Society was held in the Winter Gardens, Cheltenham, on the above dates, and may be described

as one of the best exhibitions the Society has held, having regard to the number of the entries and the good quality of the exhibits. Rain fell heavily on the opening day, and somewhat lessened the attendance of the public.

For six stove and greenhouse plants in bloom, Mr. J. Cypher, Queen's Road, Cheltenham, was 1st, with very fine specimens of *Erica Marnockiana*, *Bougainvillea glabra*, *Clerodendron Balfourianum*, *Allamanda nobilis*, *A. Hendersoniana*, and *Stalice profusa*, all of them finely-bloomed; 2nd, Messrs. Heath & Son, Cheltenham, with *Allamandis*, *Ixora Dullii*, and *Stalice imbricata Gilbertii*, as their best examples.

The competition for thirty plants, in or out of bloom, is a prominent feature at these shows, and some very large specimens were shown in this competition. Mr. Cypher exhibited some of his large Palms and Crotons, and was much ahead of all his rivals with beautifully-coloured Crotons, with *Kentias*, *Latanas*, *Cycas revoluta*, and *C. undulata*; a grand plant of *Cordyline indivisa*, also *Allamandas*, *Anthuriums*, and other plants in flower; 2nd, Messrs. Heath, with plants which were smaller, and the best of which were the *Kentias*, *Croton Weissmanii*, *C. Youngii*, *C. Victoria*, and *Phenocoma prolifera Barnesii*.

For collections of Exotic Ferns, Mr. Cypher was 1st, with very fine specimens, such as are rarely seen. These consisted of *Adiantum Farleyense*, *A. cuneatum*, *A. gracillimum*, *Neottopteris nidus avis*, a grand piece of *Cibotium princeps*, and *C. medullaris*; 2nd, Mrs. Heath, with nice plants of *Cibotium Schiedeii* and *C. princeps*; *Dicksonia antarctica*, and *Gymnogramma peruviana*.

Collections of British Ferns.—Messrs. Heath & Son were 1st, and Mr. C. Lockyer 2nd.

The competition in the classes for Roses, annual Asters, Gladioli, Hollyhocks, was in some cases severe, the flowers generally being of fine quality, and as regards the Roses, they were very good for the season.

Zonal Pelargoniums, tuberous-rooted Begonias and Fuchsias were fresh and well-flowered, but there was nothing of special merit amongst them to call for notice.

The class for blooms of hardy herbaceous was a very fine one, Mr. Cypher being 1st, Messrs. Heath, 2nd, and Mr. Marsh, Arle Court, 3rd.

FRUIT.

The fruit classes were well filled, and the various exhibits meritorious. Rev. G. Coventry (gr., Mr. James), was 1st for two dishes of black Grapes, six bunches; Mr. Armstrong, Winchcombe, 2nd; Mr. Lee Campbell, 3rd. For a single dish of three bunches, 1st, Lord Sudeley, Toddington (gr., Mr. J. Clear); 2nd, Major Palairret, Ledbury. Two dishes of white Grapes, six bunches, 1st, Mr. J. Clear; 2nd, Mr. L. Campbell; for a single dish of white Grapes, Mr. Marsh, 1st; and the Rev. Canon Coventry, Worcester, 2nd.

Collections of fruit, to consist of eight dishes, the Earl of Coventry, Crome Court (gr., Mr. Child), was 1st, having very fine black Grapes, Figs, Melons, Peaches, and well-finished examples of Muscat of Alexandria Grapes. The 2nd prize collection—that shown by H. C. Moffatt, Esq., Goodrich Court (gr., Mr. Spencer)—ran this one very close, and contained several very fine dishes. Lord Sudeley's gardener had to be content with the 3rd place.

The Rev. G. Coventry, Colonel Rogers, and Major Palairret took the prizes in the order of their names for the best of the collections of four dishes of fruits, distinct kinds.

Nectarines, Melons, and Morello Cherries were all good. Dessert Apples were well shown by Messrs. Cook, Smith, and Heath; and cooking varieties by Messrs. Garraway (Bristol), Cypher, and Hall. Plums were abundantly shown, the best coming from Mr. Lee Campbell, Earl Coventry, and Lord Sudeley.

Collections of Apples in the amateur's classes made a large display, Earl Coventry being 1st with large well-coloured fruit; 2nd, Mr. Hall.

Pears were abundant, and Mr. Smith and Mr. Howell were the exhibitors who showed best.

Vegetables showing much good culture occupied a large amount of space, Mr. Garraway being 1st; and Mr. Cook 2nd for nine kinds; and Gen. Little (gr., W. Davie), 1st; and J. R. Grentorex, Shrewsbury, 2nd, for six kinds.

Tomatoes were fine and numerous, as were the exhibits of Potatoes.

NATIONAL CHRYSANTHEMUM SOCIETY.

SEPT. 28.—A meeting of the Floral Committee of the above took place at the Royal Aquarium, Westminster, on the above date, and though, as is usual this month, but few flowers were exhibited, these were of an interesting character. From Mr. S. Dibbena, florist, Brockley, came Japanese Amy Chantler, golden centre, with pale lilac and creamy petals, a reflexed variety. Mr. Adams, Fortia Green, Finchley, sent Japanese Mary Adams, a small reflexed yellow Japanese, which the Committee desired to see again. A First-class Certificate of Merit was awarded to Mr. R. Owen, nur-

bore testimony to the fact that it is a peculiarity of the flower to come in this character. Mr. Davis also had a bunch of the early white-flowered Mrs. Cullingford, to show its fine character; and stated that this and La Vierge, were the two best white early-flowering Chrysanthemums in cultivation, an opinion that appeared to be endorsed by the floral committee.

LOCAL SHOWS.

THE BILDESTON DISTRICT HORTICULTURAL AND INDUSTRIAL ASSOCIATION held their twenty-seventh annual show on Friday, September 16. The exhibition was favoured by charming weather, and was

before a large audience. The lecturer spoke for more than an hour upon the various insect pests which during the present season have been so prevalent in Leicestershire, carefully pointing out the best means of exterminating the same. At the close many questions were asked, and were readily answered by Mr. Walker.

THE TORQUAY DISTRICT GARDENERS' ASSOCIATION is now an accomplished fact. It is a new movement, designed to promote the welfare and improvement of gardeners by occasional meetings to discuss matters of special interest. Mr. F. C. Smale, the energetic Hon. Treasurer and Secretary, has arranged a varied and interesting programme, which is to be opened the first Friday in October by a paper by the President, Mr. W. Lavers, on "Gardens, Glass-houses, and Flowers, especially Orchids," of which he has a rare collection. Mr. Jones, of The Cedars, follows the next meeting with an essay on "The Bouvardia: its history, culture, and usefulness;" and Mr. W. B. Smale concludes the month with an account of "A Visit to the Dutch Bulb Farms." In November, Mr. French, of Rooklands, and Mr. Searle, of Graton, speak on Roses and Chrysanthemums, and the next month Mr. Stacey, of the Elms, is to say something about the Peach. A social gathering is to be held early in the New Year, after which Major Grahame has promised to describe "How we Garden in India." In February, Mr. Hodder, of Ponsonby, will introduce a discussion on natural and artificial fertilisation; and Mr. Neate, of Rocheard, on the cultivation of the Grape. Mr. Satterley, of Braddon Villa, opens March with a talk about the Begonia; and Mr. Hebba, of Hen-napyn, follows with some information about hardy flowers; the programme concluding with an interesting debate on that increasingly popular vegetable, the Tomato, led off by Mr. Hodges, of Watcombe Lodge. With such a syllabus, the Association deserves every success.

SCOTSWOOD FLOWER SHOW.—On Saturday, the members of the Scotswood Floral and Horticultural Society held their ninth annual show near the railway station at Scotswood. As good a prize list was issued as in previous years, and a large number of entries were secured in many of the classes. The hardiest and more easily-grown flowers were forward in large numbers. The Roses exhibited were not only numerous but also fine in quality, the best being those of M. Wheatley, of Greenside. Asters, Pansies, and Dahlias covered a large amount of space, and fine specimens of each were shown. The premier awards were secured by J. Gardner, Whickham; G. Davison, Eachwick; and J. Spoor, Scotawood, respectively. G. Rayner won 1st prize for bouquets.

HARDY SHRUBS.

Olearia Haasti.—Few of the Olearias can be termed hardy, some requiring the protection of a greenhouse, while others may be planted against a wall with partial success; but the one now under notice is perfectly hardy, having withstood the rigours of past winters unprotected. It is a native of New Zealand, and was introduced into English gardens by Messrs. Veitch, of Exeter, thirty-four years ago. It belongs to the great Composite family, and flowers during August and September, a time when there is a dearth of flowers on trees and shrubs, a point much in its favour. It forms a compact evergreen bush of about 5 feet in height, plentifully supplied with strong shoots, thickly set with Myrtle-like foliage, light green above and silvery-white beneath. Its Daisy-like flowers are carried in dense clusters so freely as to almost cover it, and these appear when the plant is quiet young. All the pruning which it needs is to thin out the growths, which would otherwise unduly crowd the centre of the bush. It should have plenty of space to grow in, and a fair amount of sunshine, and it may then be trusted to afford a good floral display. A good effect is obtained if Gladiolus, or the short-growing *Lilium tigrinum splendens*, and others, are placed near or between the plants. The plant is not fastidious as to soil, but that in which it thrives best is an open loam, the growth being then much stronger than when it is grown in peat soil. It is a serviceable plant for the sea-coast. Propagation is best effected by means of cuttings taken off in the early autumn, and dibbled into prepared sandy soil on a warm border, and covered with hand-

FIG. 67.—*DYMENANDRA CRASSIFOLIA.* (SEE P. 412.)

seryman, Maidenhead, for General Hawkes, a fine October-flowering Japanese, colour rich amaranth, with silvery reverse, very fine and striking. Mr. Owen also had Galaxy, a white and pink-flowered Japanese, very free; and Madame Zephyr Lionnet, rich golden yellow, the young blooms tipped with brown—very free, and a fine decorative variety, commended for its colour. A First-class Certificate of Merit was awarded to Mr. Davis for Gloire de Mezin, a reflexed Japanese, deep buff, with orange-salmon centre, fine and bright, the flowers deep and full. Mr. Davis also had George Woodgate, a reflexed mauve-pink Japanese, but somewhat flat as shown; which the Committee wished to see again.

Mr. Davis brought flowers of Bouquet de Dame, a white Japanese, and said that as it had a tendency to throw hairy florets, it might be produced in the latter character as a new variety. Other growers

quite equal to any of its predecessors. The prizelist, which was large, included classes for growers for sale, private growers, amateurs, and tradesmen, labourers, and cottagers, and a separate department for industrial exhibits.

NEWCASTLE-ON-TYNE.—The first exhibition of a Society that has been formed in the east end of Newcastle, was opened on Saturday, September 17, and remained open until Monday evening. The exhibition was considered highly satisfactory, and earnest hope was expressed that the Society should meet with continued success.

HUGGLESCOTE, LEICESTER.—*Lecture on Horticulture.*—On Thursday evening, Mr. J. H. Walker, who is engaged to lecture on Horticulture by the County Council, delivered the third of a course of four lectures on that subject in the National School

lights. They must be watered overhead with a fine-rose can occasionally, and shaded from the direct rays of the sun. By the following May the cuttings will have made roots, and can then be planted out in nursery rows.

HYMENANTHERA CRASSIFOLIA (SEE FIG. 67, P. 411).

Although known to English gardens since 1875, it is seldom met with. It forms a low, freely-branched evergreen shrub, rarely exceeding 3 to 4 feet in height, with stout branches clothed with small leathery leaves, arranged alternately along the shoots, and measuring from half to three-quarters of an inch long. Its flowers are small, and of a yellowish tint, followed by snow-white berries, about the size of those of the *Pernettyas*. In the South and South-west of England it is hardy, but farther north it requires some little protection during the winter. To grow this New Zealand shrub well, it should be planted in well-drained peaty soil, and the situation should be sunny. Being low-growing, it makes an admirable plant for the rock-garden, or as a front line in shrubberies. It is a member of the Violet family. The stock is readily increased by pieces of the half-ripened wood, cut below a joint and placed round the sides of 5-inch pots in light sandy soil, and the pots plunged in close propagating cases, and in a few weeks' time, roots will be emitted. *H.*

THE BULB GARDEN.

HARDINESS OF GLADIOLI.

SOME time ago, Mr. Chinnery in a note on this subject, omitted to say at what depth he plants his Gladioli. The whole question of hardiness so far as *G. Breuchleyensis* is concerned depends upon their being out of reach of the frost; whether they will bear planting at such a depth and thrive as well as if nearer the surface, is the point to be considered. I always prefer keeping them in the ground during the winter to storing them on dry shelves; and in order to make them safe, we lift them from the Rose-beds and place them close together in a sheltered place about 6 inches below the surface, and then put about a foot of long litter over them; but if they will succeed when planted deeply, we might save the labour of lifting and replanting at least once in two years. *W. H. Divers, Ketton Hall Gardens, Stamford.*

ROUND LIVERPOOL.

THE LIVERPOOL HORTICULTURAL CO. (LIMITED).—Under the management of Mr. John Cowan, the nurseries at Garston, Liverpool, are widely known, the weekly special offers of Orchids, &c., which are so persistently sent to all growers, and which are so varied in the assortments of plants enumerated, and so moderate in price that few there are (among Orchid growers at least) who have not had dealings with the firm. The large nursery, originally devoted to the culture of Vines, a culture which is still largely maintained, added to its specialty, the culture of Tea Roses in pots, and especially of *Maréchal Niel* and other climbing varieties, thousands of which are now to be found in the large and lofty houses set apart for them, then took up the importation of Orchids on an extensive scale, and at present that branch of the business takes the lead, the whole of it being under the supervision of that well-known and able plant-grower, Mr. John Baguley, for some years with Mr. Wm. Bull at Chelsea. In quantity the stock of Orchids at Garston is so extensive as to preclude the possibility of touching only on some of the more important batches. It will be noticed that the quick sale, which is the object of the company, forbids the presence of any great number of old-established plants, and consequently the bulk is made up of either fresh-imported or semi-established plants, and none could be more convenient for the amateur of limited means or the trader who wishes for sound plants to grow on.

Let us take a look through the houses and note the more striking batches. In the first large span-roofed house was a splendid lot of specimens of *Ceologyne cristata*, and *C. c. Lemonians*; a few fine exhibition Orchids, among which were a very large and healthy *Sobralia macrantha*, a fine *Angraecum eburneum* with three spikes; the true *Cypripedium longifolium grandifolium*, *Dendrobium Parishii*, and *D. Loddigesii*. In the large Cattleya-house were some splendid *Lælia crispa*, a noble variety of *Lælia elegans* Turneri, a few great masses of *Cattleya Walkeriana nobilior*, a grand lot of the true old autumn-flowering *C. labiata*, both imported direct, and acquired from all the other firms who have got it over; *Cattleya Leopoldi*, and a large quantity of *C. Trisnæ* in sheath.

Passing through a cool lean-to house full of *Odontoglossums* and *Masdevallias*, we go to another lean-to on higher ground, running at right angles to it, and being in a sunny aspect. Here the *Lælia majalis* and *Cattleya citrina* are in grand condition, and have been flowering profusely. It is said that upwards of 400 flowers have been produced by the plants of *Lælia majalis* alone. They and the *C. citrina* are suspended over the entire roof, and during the summer they have never been dipped, but have been kept moist by being frequently syringed—a method which has suited them perfectly well. Many other Mexican Orchids in this and in the other houses are treated in a similar manner, with equally good results. Next, we come to a block of four houses, in the first of which were a quantity of *Sophranitis cernua*, *Colax jugosus*, and *Odontoglossum maculatum*, which have yielded fine forms of the *O. m. anceps* class.

In the second, among other things, are good *Odontoglossum Harryanum*, *O. citrosimum*, *Oncidium varicosum*, and *O. sarcodes*. The third, a showy lot of *Odontoglossum grande*, with many in bloom; and the fourth, a reputedly new *Aërides*, with white flowers, a new *Sobralia*, a good lot of *Cypripedium exul*, and a large quantity of *Vanda Denisonii* attract the eye.

Another large span-roofed hot-house has the roof covered with *Rodriguesia pubescens*, *Dendrobium Brymerianum*, *Oncidium papilio*, *Houlletia Brocklehurstiana*, and *Angraecums*; here one specimen of *Saccolabium Blumei* has borne twelve spikes. In a sheltered corner are a very flourishing set of *Phalaenopsis*, and a good part of the rest of the house is occupied by seedling *Cypripediums*. Other noteworthy specimens are a very large *Vanda tricolor insignis*, a strong specimen of *Renanthera Storyii*, some large *Aërides*, *Dendrobium Devonianum album*, *D. Cassiope* ×, &c.

The large block of five houses, each about 180 feet long and 20 feet wide, has hanging from the roof of the first of them an almost uncountable host of Mexican *Lælias*, some of the specimens of *L. anceps* (both white and coloured) and of *L. albidula* being 3 or 4 feet across. The whole of the coloured forms are of the *L. anceps Morada* or *grandiflora* type, which the Liverpool Horticultural Company were fortunate enough to introduce, and which has yielded the largest and richest-coloured forms of the species in cultivation. In this house the *Barkerias* flourish; *Chysis lævis* is in quantity; *Mormodes citrina* and *M. pardina* plentiful, and *Lælia superbiens*, and other light-loving species in fair quantities. The roof of the next bears thousands of *Cattleya citrina* and *Odontoglossum Rossii majus*; and among fresh arrivals a fine importation of a supposed new *Zygopetalum*, *Cattleya Alexandræ*, and *C. Acklandiæ*; *Oncidium ampliatum majus*, and large healthy masses of an unknown *Sobralia*, which have come over in remarkably good condition. Another house is nearly filled with *Cattleya Mendelii*; then we come to a large lot of *Lycaste Skiuneri*, the true *Oncidium falcipetalum*, *O. macranthum*, *O. Gravesianum*, and others of the *O. crispum* section; a few of the rare *Odontoglossum Galeottianum*, and a large quantity of *O. Cervantesii* and *O. C. mosada*, or *lilacina*; then come *Cattleya gigas Sanderiana*, *Vanda cœrulea*, *Ceologyne*

pandurata, and other showy Orchids, in bewildering variety.

In the large and lofty houses in which the Vines in pots are grown, and which necessarily require a good space between the pots, the room on the staging between them is utilised for growing the stronger *Dendrobes*. Probably the practice was commenced at first from the necessity of accommodating fresh arrivals, but the plan is found to answer very well and so grown are the whole of the showy *Dendrobes* to be found at Garston. Among them that general favourite, *D. Phalaenopsis Schroderiana*, is one of the freest, and other of the rare varieties of *D. nobile*, *D. Ainsworthii*, &c., are here propagated from cuttings by Mr. Baguley with great success.

In the many other houses are grown *Eucharis*, *Pancratiums*, Ferns, and other plants suitable for cutting, for there is a shop in town and stand in the market to keep supplied, a fact which accounts for the scarcity of flowers to be seen in proportion to the great number of plants.

The old vineries have their roofs covered by the canes of the original *Madresfield Court Vine*, which was planted many years ago, and which this year, as in former years, has had its crop restricted to 500 bunches, a quantity which it carried and finished well.

(To be continued.)

NURSERY NOTES.

BEGONIAS AT SWANLEY.

THE nurseries of Messrs. H. Cannell & Sons are looking gay, both inside and out, with both single and double Begonias, of all shades of colour. Of the doubles, for pot culture, *Octavie*, a pretty dwarf-growing variety, with pure white flowers, seems to be a favourite. Outside, numbers of seedlings are planted out, a portion of which are especially good. The seed was sown late last autumn, and not allowed to flower, but lifted, stored, and planted again. This spring they were good healthy plants, carrying a quantity of very fine blooms, chiefly double. There is also a good show of *Dahlias*, of the best sorts, including amongst others, *Maid of Kent*, cherry red, crimson ground, with white tips; *Cannell's Favourite*, old gold; *Annie Harvey*, rich crimson-maroon; *H. Cannell*, dark velvety crimson; *Panthea*, good, salmon-red: all very showy varieties. *E. Hewitt, Fulham Palace, S.W.*

CULTURAL NOTES.

LILIUM AURATUM.

I HAVE flowered here this season a single bulb of the above Lily with one shoot only, carrying in all twenty-two fully-developed flowers. As beautiful as Mr. Kempshall's display must have been, what a glorious sight would his Lily with forty shoots have been if each had shown twenty-two blooms!

My practice is simple. In early spring, I divest the bulb of every particle of soil, and pot it in good loam and leaf-mould, with a fair sprinkling of silver-sand. When the plant is about 3 feet high, I repot into a size-larger pot, and when that is full of roots, a considerable quantity of manure-water is afforded. *R. Nelson, Hwith House, Ravenstonedale, Westmorland.*

ENQUIRIES.

"He that questioneth much shall learn much."—BACON.

THE SALMON BERRY.—The rauchers in Oregon always speak of the Salmon Berry, which I suppose is *Rubus spectabilis*, as being a most delicious juicy fruit—too juicy to preserve, in fact. There are two varieties, one bearing a yellow and another a pinkish berry. Has it ever been cultivated with success in England? *Vagabond.*

MARKETS.

COVENT GARDEN, September 29.

[We cannot accept any editorial responsibility for the subjoined reports. They are furnished to us regularly every Thursday, by the kindness of several of the principal ealesmen, who revise the list, and who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the supply in the market, and the demand; and they fluctuate, not only from day to day, but often several times in one day, Ed.]

MARKET well supplied, with trade still dull, James Webber, Wholesale Apple Market.

FRUIT.—AVERAGE WHOLESALE PRICES.

Table with columns for fruit types (Apples, Grapes, Keat Filberts, Lemons) and prices per unit.

PLANTS IN POTS.—AVERAGE WHOLESALE PRICES.

Table listing various plants in pots (Adiantum, Aspidistra, Ferns, etc.) and their prices.

CUT FLOWERS.—AVERAGE WHOLESALE PRICES.

Table listing cut flowers (Arum, Asters, Carnations, etc.) and their prices.

ORCHID-BLOOM IN VARIETY.

VEGETABLES.—AVERAGE RETAIL PRICES.

Table listing various vegetables (Artichokes, Beans, Beet, Carrots, etc.) and their retail prices.

POTATOS.

Market very quiet; even fresh arrivals are slow to attract buyers. Prices from the best bright soils, 60s. to 70s.; from dark soils, 45s. to 55s. Immediate prospects not favourable. J. B. Thomas.

SEEDS.

LONDON: Sept. 28.—Messrs. John Shaw & Sons, Seed Merchants, of Great Maze Pond, Borough, London, S.E., report some business doing in fine yearling Red Clover seed. Small sowing orders are still received for Trifolium; prices continue to advance. Winter Teas meet a steady inquiry at former rates. Sowing Rye continues cheap and good. French Italian is getting dearer. As regards Canary seed, Liverpool advices come firmer. There is no change in Hempseed. Linseed is steadier. The new blue Peas show fine quality, and meet with considerable favour. Haricot Beans offer at tempting figures. Mustard and Rape seed are unaltered.

HAY.

Averages.—The following are the averages of the prices obtained at the principal metropolitan markets during the past week:—Clover, prime, 80s. to 112s.; do., inferior, 46s. to 75s.; Hay, best, 80s. to 105s.; do., inferior, 26s. to 50s.; and Straw, 28s. to 40s. per load.

FRUITS AND VEGETABLES.

BOROUGH: Sept. 27.—Quotations:—Cabbages, 2s. 6d. to 3s. 6d.; Marrows, 3s. 6d. to 4s. 6d. per tally; Cauliflowers, 1s. 6d. to 1s. 9d. per dozen; Lettuce, 6d. to 1s. per score; Carrots, 2s. 6d.; Turnips, 1s. 6d.; Parsley, 2s. per dozen bunches; English Onions, 4s. to 4s. 6d. per cwt.; Horseradish, English, 2s. 6d.; foreign do., 2s. per bundle; English Apples, 2s. 6d. to 5s. per bushel.

SPITALFIELDS: Sept. 27.—Quotations:—Cabbages, 2s. 6d. to 6s.; Marrows, 3s. 6d. to 6s.; Cauliflowers, 2s. 6d. to 6s. per tally; Brussels Sprouts, 1s. 6d. to 2s. per half-sieve; Spinach, 1s. to 2s. per bushel; Greens, 1s. 6d. to 2s. 6d.; Carrots, 1s. 6d. to 2s.; Turnips, 2s. to 3s. 6d.; Onions, 2s. to 3s.; Parsley, 1s. to 1s. 6d. per dozen bunches; Scarlet Beans, 1s. 6d. to 2s. 6d. per bushel; Celery, 6d. to 1s.; Horseradish, 1s. to 1s. 2d. per bundle; frame Cucumbers, 1s. 9d. to 2s. 6d.; Endive, 4d. to 8d.; Cabbage Lettuce, 2d. to 4d. per dozen; Cos Lettuce, 4d. to 10d. per score; Spanish Onions, 5s. to 6s. per case; Belgian do., 2s. 9d. to 3s. 6d.; Dutch do., 2s. 9d. to 3s. 6d. per bag of 110lb.; Seakale, 9d. to 1s. 3d. per punnet; English Apples, 2s. 9d. to 6s. per bushel; English Tomatoes, 5s. to 6s. per peck; foreign do., 1s. 8d. to 2s. 6d. per case; Damsons, 2s. 6d. to 3s. per bushel; Plums, 1s. 9d. to 2s. 6d. per half-sieve; Leeks, 1s. 9d. to 2s. 6d. per dozen bunches.

STRATFORD, Sept. 28.—There has been an excellent supply of all kinds of produce at this market during the past week, and a brisk trade was done as under:—Cabbages, 2s. to 4s. per tally; Cauliflowers, 9d. to 1s. 6d. per dozen; do., 4s. to 7s. per tally; Beans, Scarlet, 1s. 6d. to 2s. 6d. per sieve; Celery, 9d. to 1s. per roll; Turnips, 1s. 6d. to 2s. per dozen bunches; do., 3s. to 50s. per ton. Carrots, 35s. to 50s. per ton; Mangolds, 17s. to 20s. do.; Swedes, 20s. to 25s. do.; Onions, Dutch, 4s. to 5s. 3d. per bag; do., Bordeaux, 7s. to 7s. 6d. per case; Apples, English, 2s. 6d. to 7s. per bushel; Plums, 1s. 6d. to 2s. 3d. per half-sieve; Pears, 2s. 6d. to 4s. 6d. do.; do. 5s. to 9s. per bushel; Carrots, 2s. to 2s. 6d. per dozen bunches.

FARRINGTON: Sept. 29.—Quotations:—Carrots (bag), 5s. per ton; Cauliflowers, 5s. per tally; Cabbage, pickling, 1s. per dozen; Turnips, 2s. 6d. per bag; Apples, cooking, 3s. per bushel; do., Ingestre, 6s. do.; Pears, Cepeaumont, 6s. do.; English Tomatoes, 3d. and foreign, 2d. per lb.; Melons, Valencia, 7s. per case; Grapes, Lisbon, 10s. per box.

POTATOS.

BOROUGH: Sept. 27.—Quotations:—English Magnums 40s. to 60s.; Hebrons, 40s. to 60s.; Snowdrops, 50s. to 60s. per ton.

SPITALFIELDS: Sept. 27.—Quotations:—Bruce Magnums, 50s. to 60s.; Reading Wonder, 50s. to 60s.; Magnums, 45s. to 60s.; Sutton's Early Regents, 45s. to 55s.; Sutton's Abundance, 50s. to 60s.; Snowdrops, 60s. to 80s. per ton.

STRATFORD: Sept. 28.—Quotations:—Magnums, 10s. to 65s.; Imperators, 50s. to 65s.; Bruce Magnums, 50s. to 65s.; Maincrop, 60s. to 70s. per ton.

FARRINGTON: Sept. 29.—Quotations:—Imperators, 60s. to 70s.; Magnums, 65s. to 70s.; Snowdrops, 65s. to 70s.; Reading Giants, 65s. to 70s. per ton.

THE WEATHER.

[By the term "accumulated temperature" is meant the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named; and this combined result is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

Table with columns for DISTRICTS, TEMPERATURE (ACCUMULATED), RAINFALL, and BRIGHT SUN. Rows list districts 0-10 with corresponding weather data.

The districts indicated by number in the first column are the following:— 0, Scotland, N. Principal Wheat-producing Districts— 1, Scotland, E.; 2, England, N.E.; 3, England, E.; 4, Midland Counties; 5, England, S. Principal Grazing, &c., Districts— 6, Scotland, W.; 7, England, N.W.; 8, England, S.W.; 9, Ireland, N.; 10, Ireland, S.; (* Channel Islands.)

THE PAST WEEK.

THE following summary record of the weather for the week ending September 24, is furnished from the Meteorological Office:—

"The weather during this period was generally cloudy and unsettled, with considerable falls of rain in many parts of England, Ireland, and the north of Scotland; it was, however, comparatively bright and dry in the east and west parts of Scotland.

"The temperature continued rather below the mean in Ireland and Scotland, and was slightly below in 'England, N.W.' also; over the greater part of England, however, it just equalled or slightly exceeded the normal. The highest of the maxima were recorded, as a rule, during the earlier days of the week, and ranged from 72° in 'England, S. and S.W., and 71° in the 'Channel Islands,' to 63° in 'England, N.W.,' 62° in 'Ireland, N. and Scotland, N.,' and 61° in 'Scotland, W.' The lowest of the minima were registered on the 18th over England, on irregular dates in Ireland, and on the 21st in Scotland. They were very low for the time of year, the sheltered thermometer falling to 25° in 'Scotland, E.,' and to between 28° and 31° in most parts of Great Britain. In the 'Channel Islands,' however, the lowest reading was 46°.

"The rainfall was more than the mean in 'Scotland, N.,' 'England, E.,' the 'Midland Counties,' and 'England, N.W.,' as well as in 'Ireland, S.;' while in 'England, S.,' the actual fall and the mean were identical. In all other districts the fall was less than the normal.

"The bright sunshine exceeded the mean in Scotland and the Channel Islands, but was below it in nearly all other parts of the Kingdom. The proportion of the possible duration, which was actually recorded, ranged from 52 per cent. in the 'Channel Islands,' and 41 per cent. in 'Scotland, E.,' to 23 in 'Ireland, S.,' 22 in 'England, E.,' and 20 in the 'Midland Counties.'"

NOTICES TO CORRESPONDENTS.

* PHOTOGRAPHS, DRAWINGS, OR SPECIMENS.—We shall be pleased to receive from our Correspondents notes relating to interesting Gardens, together with Specimens or Illustrations of interesting Plants. Although circumstances prevent us in all cases from reproducing them, we are nevertheless glad to receive them, and as far as possible to utilise them for the benefit of our readers.

AUSTRALIAN GARDENING PAPERS: Andersson. The Horticulturist, New South Wales; The Queenslander and Planter and Farmer, Brisbane. Apply to some foreign newsagent or bookseller.

BEES: G. B. For feeding bees, see p. 407, in this issue. The hives need not be taken indoors. Wooden hives or straw skeps may have a piece of carpet placed on the top, and this may be covered with a bit of oil floor-cloth. The cooler bees are kept whilst at rest the better.

BLUE OR SPECKLED-PODDER FRENCH BEANS: Hants. These, with others, were shown by Mr. Barron, from the Royal Horticultural Society's Garden, Chiswick.

BOOKS: Amicus. Do not waste your time over the Linnean system; Henfrey's Elementary Course of Botany will meet your requirements (Gurney & Jackson, Paternoster Row).—W. J. C. The Student's Flora, by Sir J. D. Hooker, C.B. (London, Macmillan & Co., Bedford Street, W.C.), price, a few shillings. Index to English Botany, by Mr. N. E. Brown (Bell & Co., York Street, Covent Garden, W.C.).

COUVE TROCHUDA: Old Bumble. It may be cooked exactly like Cabbage, rejecting the outer leaves; or the ribs of the leaves may be cooked after the manner of Seakale, and served like that in a sauce. It is excellent either way. It requires no blanching; still some growers tie the leaves together like Lettuce, to increase the quantity of edible leaves.

CUCUMBER ROOTS: L. S. D. Your roots are badly affected with the eel-worms, so very often figured and described in our columns. Burn the plants, turn out all the soil, and start afresh.

FORAGE PLANTS OF AUSTRALIA: See Gardeners' Chronicle for August 27, 1892, p. 245, for a notice of this book.

GOOSEBERRY BUSH: W. N. The stem is dead, but the roots are fresh-looking, and exhibit no disease. The plant has evidently died downwards, and without further information we are unable to form any opinion as to the cause or causes which have occasioned the loss of the plants.

CARNATION: *G. W.* A good specimen of the old Wheat-eared Carnation, in which, for some mysterious reason, the flowers are not formed; but the bracts, which usually form at the base of the

FIG. 68.—Multiplication of bracts, sepals, &c., of Sweet William.
(See Wheat-Eared Carnation.)

calyx, are repeated an indefinite number of times. It is a curiosity which a florist would think little of, but in which a botanist would be much interested.

GRAPE WINE: *A. H. C.* Smash the berries, macerate them in water at the rate of 3 or 4 lb. to the gallon of spring-water. In four days strain off the liquor, squeezing the fruit dry. Add to each gallon 3½ lb. of loaf or moist sugar according to fancy, and keep it in an open vessel till fermentation takes place. This will be in two or three days if the temperature is kept at 65°. Let the yeast rise for two or three days, skimming it off daily; then run the wine into casks or large stone-bottles to still further ferment. If a "still" wine is wanted, let the fermentation entirely cease before bunging down; if effervescing, bung down whilst there is yet some slight amount of ferment; and for the latter very strong bottles or casks are needed. Rack off as soon as cold weather sets in, and again the following March; keep it cool. Price of Grapes (foreign) at this part of the season 4d. to 6d. per lb. These would need no sugar.

HORTICULTURAL INSTRUCTION: *F. P.* Apply to the Director, Royal Botanic Garden, Edinburgh.

INSECTS: *B. F. L.* A mite allied to the red-spider. It is known as the Lime tree mite, *Tetranychus tiliarum*.—*E. M.* What you send are the grubs or larvæ of some species of wire-worm, *Iulus*. Try the application of gas-lime to the soil.

NAMES OF FRUITS: *Alpha.* 1. Adam's Pearmain; 2. N-w Hawthornden; 3. Beauty of Kent; 4. Gravenstein; 5. Bedfordshire Foundling.—*Thos. Adcock.* 1. Peach Noblesse; 2. Apple Summer Thortie; 3. Lord Suffield; Pear not recognised.—*Inquirer, Ross.* 1. Doyenné Bussouch; 2. Duchesse d'Angoulême; 4. Burié Hardy; 5. White Doyenné; 6. Fondante d'Antoine.—*Thos. Imrie & Son* Pear not known—an old Scotch variety.—*C. Wood.* 1. decayed; 2. Warner's King; 4. Schoolmaster; 7. Scarlet Nonpareil; others not recognised.—*Rob Roy.* 1. Duchess of Oldenburgh; 2. probably Dutch Codlin; 3. Red Quarrend; 4. Ravelston Pippin; 5. King of the Pippins; 6. Stirling Castle; 7. Cambuethan Pippin; 8. Rymer; 9. Waltham Abbey Seedling; 10. Queen Caroline; 11. Irish Peach.—*James Young.* 1. Beauty of Kent; 2. Damelow's Seedling; 3. Col. Vaughan.

NAMES OF PLANTS: *C. B., Paris.* *Cypripedium Madama* Cappé is *Spicerianum* × *Dautierii* and *C. Kirchoffianum* *Dautierii* × *Spicerianum*. These are continental. *C. Eymannianum* (Sander) is *Spicerianum* × *barbatum grandiflorum*.—*H. F. E.* 1. *Euonymus laetivius*; 2. *Campanula isophylla* alba; 3. *Amelanchier vulgaris*; *Convolvulus sepium*, large white flower, or *C. arvensis*, small pink flower.—*Muscat.* 1. *Begonia discolor*; 2. *Yucca*, probably, send when in flower; 3. *Platystemon californica*; 4. *Croton* var.; 5. *Symphoricarpos racemosus*; 6. *Panicum sulcatum*; 7. is a case of "rust," caused either by cold draughts of air, or by being closer than the other bunches to sulphured

hot-water pipes; 8, shows shanking, which is usually a root malady, or the result of some sort of check to growth; 9, seems to be an exaggerated form of rust.—*J. M.* 41. 11, 'Too shrivelled to identify; 23. *Polystichum angulare* var. *grandiceps*, *J. Jones*; 160, *P. angulare* var. *lineare*; No. detached and missing, *Lastrea p. m. cristata*.—*G. W.* *Colutea arborescens*, a very old plant, excellently suited for growth in towns.—*W. H. P.* *Hedychium Gardnerianum*, nearly hardy under protection; cultivation very simple, in good sound loam and manure. Should be kept in a dryish state during the winter in pot or border. Do not afford much water at the root after this date.—*T. W. R.* 1, *Crataegus coccinea*; 2, *C. punctata*; 3, *C. coccinea* var.; 4, *C. macracantha Rosaceæ*—*W. T.* 1, *Berberis vulgaris* (*Berberidaceæ*); 2, *Rhus cotinus* (*Anacardiaceæ*); 3, *Lycycteria formosa* (*Caprifoliaceæ*); 4 *Ligustrum sinense* (*Oleaceæ*); 5, *Colutea arborescens* (*Leguminosæ*); 6, *Clematis cirrhosa* (*Ranunculaceæ*).—*W. C.* 1, *Chrysanthemum lacustris*; 2, *Helianthus multiflorus*; 3, *Eupatorium cannabinum*; 4, *Sedum spectabile* (*Crasulaceæ*); 5, *Helianthus Maximilianus*; 6, *Pyrethrum uliginosum*; 7, *Bocconia cordata* (*Papaveraceæ*); 1 2, 3, 5, 6, all *Compositæ*.—*Wm. W.* It is *Rodriguezia pubescens*.—*W. W. T.* 1, *Polystichum aculeatum*; 2 *Athyrium filix-œmina*; 3, *Polystichum angulare*; 4, *Cyatopteris fragilis*.—*J. H., Norwood.* 1, *Nephrolepis rufescens tripinatifida*; 2, *Asplenium tenuicolum*; 3, *Davallia bullata*; 4 and 5, probably forms of *Adiantum cuneatum*; 6, *Davallia immersa*; 7 *D. canariensis*.—*J. M.* *Gymnogramma ochracea*; 2. *Polypodium* sp. Seed fertile frond; 3 *Leucostegia* (*Davallia*) *immersa*.—*G. S.* *Ocoidium flexuosum*.—*A. H.* *Cypripedium Spicerianum*—*J. Moore.* 10. *Scolopendrium vulgare corymbiferum*; 15. *S. vulgare* *isum*; 18, *Athyrium filix-œmina cristatum* var.; 20. *Polypodium cambricum*; 30. *Allosorus crispus*; 90. *Lomaria spicata imbricatum*.—*W. Dann.* 2, *Doryopteris palmata*; 3, *Doodia caudata*; 6, *Aster Linosyris*; the others are *Viburnum Opulus* and *Davallia tenuifolia*.

NATIONAL FRUIT-GROWERS' LEAGUE: *Mazagan.* We assume that you mean the Fruit-Growers' Association. Apply to Mr. T. F. Rivera, Sawbridge-worth, Herts.

MELONS: *Eureka.* The fruits sent to us exhibit the appearances often observed when the bottom-heat is too low, and the moisture at the root and in the air in excess of the needs of the plants. Were no young fruits on the plants, there might be nothing to indicate anything being wrong with the plants, but having young fruits, these are the first to show signs of distress. You should ascertain if the bottom-heat has declined below 80°.

SEASIDE PLANTING: *Hants.* See our issue for September 3. p. 287.

SEEDLING BARIAS: *P. C.* You might obtain them from the trade, or by sowing the seeds of the Wild Rose. They are fit for Stocks in the third year. Grafting is done on the root-stock low down the roots, being either potted or bundled up in loam round which moss is secured. Winter in a close pit or house with a summer warmth of 60°, and maximum of 70°.

STONE FOR A ROCKERY: *G. R. T.* The sandstone obtainable about Rigate is very suitable for rockeries, and it is the most accessible from your place of abode. The cost of transit would be the heaviest item.

WHAT IS A DEALER? *Puzzled.* We think the framers of the schedule knew what they were about, and that they wished to draw the line between the amateur who under no circumstances grows for sale, and the dealer who sells his surplus stock. The regular nurseryman would not necessarily sell all his stock if he had the opportunity. He would reserve some for propagation. The genuine amateur is in our opinion unfairly treated when he is called on to compete with "amateur dealers."

Exhibits at Stand 1 and Insectivorous House, International Horticultural Exhibition, Earl's Court

THE IMPROVED GARDEN GULLY (VINCE'S PATENT).

This useful invention is a great improvement on the ordinary Garden Grating, and is especially suitable for hilly walks and drives. As they never get stopped by rubbish or sand they effectually prevent the washing away of the gravel in heavy storms, and they save half the labour in cleaning out the cess-pools. The prices are:—

6-in., 1s. 6d.; 8-in., 2s.; 10-in., 3s.; 12-in., 6s. 6d.; 15-in., 8s.
(The larger sizes are very strong for carriage drives.)

FIXED.

Full Particulars on application. Testimonials:—

From Mr. J. WILLARD, Head Gardener to the BARONESS BURDETT-COUTTS, Holly Lodge Gardens, Highgate, N., July 12, 1892.—"Dear Sir, Having given your Improved Garden Gully a fair trial, I may say that it proves in use all that you claim for it, and in my opinion has, for the sides of walks and drives, many advantages over the ordinary grating. Perhaps the best proof I can give you of this is that, as opportunity offers, I intend to use them instead of gratings. Faithfully yours, J. WILLARD."—To Messrs. VINCE & VINE.

From W. WALTON, Esq., Secretary, to the LONDON CEMETERY COMPANY, 29, New Bridge Street, Blackfriars, E.C., July 25, 1892.—"To Messrs. Vince & Vine, Highgate. I am very happy to testify that your Patent Garden Gully-Frames in lieu of the old fashioned gratings answer admirably. They were by my authority fixed in a new pathway made in Highgate Cemetery, and in the recent thunder showers they were severely tested and were

most effectual in preventing the scouring of the gravel. At the inspection my Directors were much pleased with them, and gave instructions that they were to be used when required at Nunhead Cemetery.—I am, yours truly, W. WALTON, Secretary."

From Messrs. CUTBUSH AND SON, Highgate and Barrot Nurseries.—"Highgate Nurseries, London, July 27, 1892.—Dear Sir,—Referring to the Improved Garden Gully you fixed for us some months ago, we are glad to say it answers admirably. As you are aware, our Nurseries here are very hilly, and during the recent storms all the ordinary gullies were blocked, whereas yours was in good working order. We shall not hesitate to recommend the same to anyone requiring the gullies for sides of paths and carriage-drives, and we feel certain, when it is known, there will be a great demand.—We are, yours faithfully, WM. CUTBUSH AND SON.—Messrs. VINCE & VINE."

THE TECHNICAL EDUCATION COMMITTEE of the BERKSHIRE COUNTY COUNCIL require, during the ensuing winter, the service of LECTURERS to deliver courses of about six Popular Lecturers in the rural districts on "HORTICULTURE." The Lecturers may also be required to visit the County in the summer months, to give practical Demonstrations in gardens, &c. Apply, with short syllabus of suggested Lectures, and stating terms to Mr. W. J. COLBOURN, Organising Secretary, 6, Russell St., Reading.

WANTED, a HEAD WORKING GARDENER, in Devonshire, with five or six under him. Must be thoroughly experienced in Flowers, Vegetables, Forcing Fruit, and Landscape Gardening. Age between 35 and 45. Married, without family, or not exceeding two. Must have unexceptionable references—Address, stating previous situations, age of self and family (if any), wages, and references, to M. L. Roberts' Library, 2, Lower Grosvenor Place, London

WANTED, as SECOND GARDENER, a married man, without family.—Must be experienced in Indoor and Outdoor Gardening; will be required to Milk, and take charge of Cows, &c.; Wife must be a good Laundress. Wages 27s. per week, with lodgings on the premises, milk, vegetables, and gas. Good references required.—Apply, by letter, to W. F., The Manor House, Richmond, Surrey.

WANTED, a GARDENER as FOREMAN, in the Houses. Roman Catholic preferred.—Wanted for the County Dublin (Ireland), a FOREMAN to take charge, under the Head Gardener, of Stoves, Green Houses and Fruit Houses. He will have two men and a boy under him. Large experience in Orchid-essentials. Wages £1 a week, share in both, milk, and vegetables (except Potatoes).—Address Messrs. TAIT AND CO., Seed Merchants, 120, Capel Street, Dublin.

WANTED, a WORKING FOREMAN, for the Indoor Department of a Botanic Garden, having practical experience of Orchids, and Stove and Greenhouse Plants. Not over 30, and must be well recommended as a good Grower. Wages 21s. per week and both in Garden.—Apply, F. W. BURBIDGE, 9, Haddington Road, Dublin.

HERBACEOUS and ROSE GROWER.—Want-d, shortly, by a well-known Firm, who are taking up Herbaceous Plants and Roses as new Departments, a capable MAN to take charge of them. Wages, 30s. per week. Apply, with all particulars to D. C., Gardners' Chronicle Office. Every application will be treated with the most honourable confidence.

Nursery Foreman. WANTED, a good ALL-ROUND HAND, under 35; must be a successful propagator and grower of good-class stock, chiefly for cut flower trade. Character for industry and sobriety must bear strictest investigation.—Apply to T. A. Wellington Street, Strand, W.C.

Assistant for Rockwork and Alpine Plants. WANTED, a young MAN, with knowledge of Plants and Propagating under Foreman, at the Broxbourne Nurseries.—PAUL AND SON, The Old Nurseries, Chesbunt, N.

WANTED, a HEAD SHOPMAN, for a Firm in the north of Ireland. Salary £100 a year. A thorough knowledge of the Agricultural Seed Department indispensable.—Apply, in the first instance, by letter only, to PETER LAWSON AND SONS, Limited, Edinburgh.

WANTED, AT ONCE, a FLORIST'S and SEEDSMAN'S ASSISTANT, young Man used to Ferns, Plants, Bulbs, Sundries, Seeds, &c.—Apply at FLORAL HALL, Richmond.

WANTED, a young MAN, in the Packing Shed, with some experience of Packing Trees and Shrubs, and a general knowledge of Nursery Stock.—Apply to WILLIAM BARRON AND SON, Elvaston Nurseries, Borrowash, Derby.

WE HAVE an OPENING for a live SHOP-MAN. Only those thoroughly conversant with seeds, Bulbs, and Garden Requisites need apply.—Address, WM. ELIOTT AND SONS 54 and 56, Dev Street, New York U.S.A.

RICHARD AND SONS, Florists, Shrewsbury, have a VACANCY for a young LADY as Indoor APPRENTICE. Moderate Premium.

WANT PLACES. TO GARDENERS, AND OTHERS SEEKING SITUATIONS.

The Pressure upon our space at this season of the year is so great, we are compelled to state that advertisements received after 6 P.M. on Wednesday will, in all probability, be held over to the next week.

Advertisers are cautioned against having letters addressed to initials at Post-offices, as all letters so addressed are opened by the authorities and returned to the sender.

TO FLORISTS.—A Young Lady, thoroughly experienced, seeks re-employment. A good hand at Wreaths, Crosses, Shower Posies, Sprays, &c. First-class references.—A. B., 110, Upper Stanhope Street, Liverpool.

HOLLOWAY'S PILLS are securities of health to all nations, of whatever climate. They give hope, relief, and comfort to millions. In irritation and debility, generated by excess of any kind, or in general prostration of the system, their effect is rapidly soothing, reinvigorating, and restorative. They rapidly drive from the system the morbid cause of ailment, and renew in the frame its pristine animation, health, and vigour. They greatly increase the appetite, give tone to the stomach, assist the digestion, and impart elasticity to the spirits; their essence enters the circulation, and carried through its course exerts its cleansing power over every organ. In the lungs they effect most striking changes, converting the impure venous into pure arterial blood, by which the whole frame is recruited.

Pears' Soap

100 YEARS AGO.—Pears' Soap in use 100 years, and still the best to-day.—100 YEARS AGO.

ODONTOGLOSSUM ALEXANDR.E.

Of the finest possible type, collected by the employees of Mr. John Carder (late of the firm of Messrs. Shuttleworth, Carder & Co.). Also a splendid lot of established unflowered ORCHIDS in the 4th or 5th year, consisting of the best forms of CATTLEYAS, LÆLIA, COELOGYNES, DENDROBES, &c.

On view morning of Sale, and Catalogues had.

Tuesday Next.

MESSRS. PROTHEROE AND MORRIS will include in their SALE on TUESDAY NEXT, October 11, 30 lots of LÆLIA ANCEPS, amongst them some extraordinary varieties—

30 lots of ONCIDIUM CAVENTISHIANUM, in very fine condition.

20 lots of ONCIDIUM REFLEXUM, fine clumps.

20 lots of ONCIDIUM ORNITHORHYNCHUM, very good.

On view morning of Sale, and Catalogues had.

Thursday Next.

100 AZALEA INDICA.

50 AZALEA MOLLIS.

100 DRACENAS, four varieties.

50 DEUTZIA GRACILIS.

100 PALMS, comprising Kentia Fosteriana, Latania borbonica, Phoenix tennens, Areca Baueri, A. Sappida.

75 PLANTS, including Aspidistra variegata, Ficus elastica, Phalangium lineare, and Aralias, from well-known nurseries in Belgium.

Also six fine plants of LAPAGERIAS, 40 lots of FERNS, 200 lots of HARDY BULBS, in variety; GREENHOUSE and OTHER PLANTS.

MESSRS. PROTHEROE AND MORRIS will SELL the above by AUCTION, at their Central Sale Rooms, 67 and 68, Cheapside, London, E.C., on THURSDAY NEXT, October 13, at 12 o'clock.

On view morning of Sale, and Catalogues had.

Friday Next.

LÆLIA GRANDIS TENEBROSA.

MESSRS. PROTHEROE AND MORRIS have received instructions from Messrs. Charlesworth, Shuttleworth & Co., of Beaton, Bradford, and 213, Park Road, Clapham, S.W., to SELL by AUCTION, at their Central Sale Rooms, 67 and 68, Cheapside, E.C., on FRIDAY NEXT, October 11, at half-past 12 o'clock, a marvellous fine consignment of the new and beautiful—

LÆLIA GRANDIS TENEBROSA,

embracing splendid specimens of unusual size, with 30, 40, and 50 bulbs.

Our collector has been the first European who has seen it in its native home. A photo. of himself and his men collecting Lælia grandis tenebrosa has been figured in the Gardening World, March 28, 1891. In appearance, the plant resembles Lælia purpurata, keeping the same character under cultivation, and is seemingly very free-flowering. The flowers are of immense size, the petals being broad, and do not reflex, as in Lælia purpurata, giving the flower a bolder appearance. The lip varies considerably; some plants have a dark purple throat, others being magenta-purple, both having white veins radiating from centre; many of the spikes show seven flower-seats.

The plant has proved itself to be of very easy culture, and free-blooming; some extraordinary fine varieties have been free-rooted out of the consignment we had last year. R. Brooman White, Esq., of Ardaraeh, showed at the Drill Hall one of the largest and finest coloured forms yet seen, and admired by everybody who saw it.

All the plants are in the best possible condition, well-leaved, and dormant; they can be recommended with every confidence. This grand novelty should be in every collection.

On view morning of Sale and Catalogues had.

Hackney, N.

Close to Hackney Downs Railway Station.

ABSOLUTE CLEARANCE SALE, WITHOUT THE LEAST RESERVE.

MESSRS. PROTHEROE AND MORRIS will SELL by AUCTION, on the Premises, the Anhurst Nursery, Anton Street, Hackney, on WEDNESDAY, October 19, at 12 o'clock, entirely without reserve, the whole of the STOCK, comprising magnificent Specimen Palms of all the leading sorts, a quantity of Ophiopogon, Draecena Lindenii, indivisa, conje ta, rubra, and others; numbers of Ferns, Phoenix reclinata, Begonia Rex, Aspidistras, Ficus elastica, specimen Scaevola, Cosmos plumosa, a fine specimen Kentia, 6 feet high, &c. Also 3 Covered Vans, including one Market Van, a large Iron Tank, &c.

On view day prior and morning of Sale.

Catalogues may be had on the Premises, and of the Auctioneers, 67 and 68, Cheapside, London, E.C.

Woking, Surrey.

A short distance from the Woking Railway Station. UNUSUALLY IMPORTANT FIVE DAYS' UNRESERVED SALE

Of exceptionally well-grown and rooted NURSERY STOCK, in the finest possible condition for transplanting, and embracing the most important lot of Stock offered by Auction for many years, the quality of which is unsurpassed in the Trade, by order of the Trustees of the late Mr. George Jackman, the land being required for Building.

MESSRS. PROTHEROE AND MORRIS

will SELL by AUCTION, on the Premises, the Woking Nurseries, Woking, Surrey, on MONDAY NEXT, October 10, and four following days, commencing at 12 o'clock precisely each day, several acres of exceptionally well-grown

NURSERY STOCK,

The whole of which is in the best possible condition for removal; comprising— 10,000 CONIFERS, 3 to 9 feet, amongst them numerous fine specimens.

Thousands of smaller EVERGREENS and CONIFERS, for Potting, &c. 1000 BOX, in variety. 10,000 Green and Variegated HOLLIES, 1 to 5 feet.

3000 LAURELS, of sorts, 1 to 5 feet, PORTUGAL LAURELS.

5000 Named RHODODENDRONS, Hybrids, &c., 1 to 3 ft.

A fine collection of ORNAMENTAL DECIDUOUS TREES, comprising Maples, Thornas, Almonds, Peaches, Planes, Poplars, &c., 7 to 10 feet.

1000 LIMES, 5 to 10 feet.

FOREST TREES in great quantities; amongst them several thousands of Sycamores, Oaks, Beech, Spruce, Limes, Poplars, &c.

5000 Common ASH, 2 to 5 feet. 40,000 QUICK, 1 to 2½ feet.

20,000 ST. JOHN'S WORT.

A splendid collection of ORNAMENTAL TREES, for Park and Avenue Planting, 10 to 20 feet, including Horse Chestnuts, Purple Beech, Scarlet Oaks, Limes, Planes, Sycamores, Maples, Elms, Poplars in variety, &c.

25,000 FRUIT TREES, comprising Standard, Feathered, and Single Corsons, Apples, Pears, Plums, and Damsons.

3000 Standard and Feathered Flowering Almonds, Peaches, Prunus Pisardi, and other Stock.

The Auctioneers have personally inspected the Stock, and desire to call the attention of intending purchasers to this important Sale. It is undoubtedly the most important Auction of Nursery Stock held for many years, and an inspection will well repay a visit by those contemplating planting during the season.

May be viewed any day (Sundays excepted) prior to the Sale. Catalogues may be had on the Premises, or of the Auctioneers, Land Agents, and Valuers, 67 and 68, Cheapside, London, E.C.

Matlock Moor, Derbyshire

GREAT SALE OF RHODODENDRONS.

MESSRS. PROTHEROE AND MORRIS are instructed by Messrs. J. Marriott & Co. to SELL by AUCTION, at their Branch Establishment, known as the Matlock Moor Nurseries, Matlock Bridge, 1½ mile from Matlock Bridge Station, on WEDNESDAY NEXT, October 12, at 12 o'clock precisely, a portion of their extensive Stock of

TRANSPLANTED RHODODENDRONS,

comprising Seedlings from the common hybrids, and also from the finest named sorts, the sizes being from two years bodded up to 2 feet high. All have been regularly transplanted, and are bushy, stocky stuff, such as can be confidently recommended to intending purchasers. Being grown on one of the highest of the Derbyshire hills, the growth is sturdy, and they are sure to succeed anywhere.

Also, by samples, 60,000 TRANSPLANTED COMMON ASH, in various sizes. The Stock will be offered in large lots, to suit the Trade and extensive buyers.

May be viewed. Catalogues may be had on the Premises; and of the Auctioneers, 67 and 68, Cheapside, London, E.C.

Havant.—Absolute Clearance Sale.

FINAL PORTION OF THE WELL-GROWN NURSERY STOCK, by order of Messrs. Ewing & Co., who are relinquishing the business.

MESSRS. PROTHEROE AND MORRIS will

SELL by AUCTION, on the Premises, The Sea View Nurseries, Havant, close to the Havant Station, on TUESDAY, October 18, at 12 o'clock precisely, without the least reserve, 5000 ORNAMENTAL, FLOWERING, and FOLIAGE TREES, a specialty at these Nurseries; 5000 Coniferæ and Evergreen Shrubs, in various sizes; 5000 Standard and Dwarf Roses; a few thousands Seedling Briar, Manetti, and Rose Stocks; 2000 Standard and Pyramid Fruit Trees, 2000 Currants and Gooseberries, 3000 Hardy Climbing Plants, in and out of pots; thousands of small Coniferæ and other Stock, for growing on; Stone and Stock Plants of Roses, Limes, Planes, &c.; Greenhouse Plants, Palms, Ferns, Azaleas, Camellias, Garden Frames and Lights, Flower-pots, &c.

On view one week prior to Sale. Catalogues had on the Premises; and of the Auctioneers and Valuers, 67 and 68, Cheapside, London, E.C.

N.B.—The FREEHOLD NURSERY to be SOLD. Particulars of the Auctioneers.

Bagshot.—Preliminary Announcement.

By order of Messrs. John Waterer & Sons.

MESSRS. PROTHEROE AND MORRIS will SELL by AUCTION, at the renowned American Nurseries, Bagshot, Surrey, on TUESDAY, November 8, and TWO FOLLOWING DAYS, large quantities of splendidly-grown NURSERY STOCK.

Descriptive particulars will duly appear.

Worcester.

FIVE DAYS' ABSOLUTE CLEARANCE SALE of about 20 Acres of beautifully-grown NURSERY STOCK, carefully prepared for removal, by order of Messrs. Richard Smith & Co., a portion of their land in the City boundary being required for Building purposes.

Important to Noblemen, Gentlemen, Landscape Gardeners, Nurserymen, and others engaged in Planting.

MESSRS. PROTHEROE AND MORRIS will

SELL by AUCTION, on the Premises, the St. John's Nurseries, Worcester, about 20 minutes' walk from the Worcester Railway Station, on MONDAY, October 17, and FOUR FOLLOWING DAYS, at 12 o'clock precisely each day, without reserve—

25,000 STANDARD and PYRAMID ORNAMENTAL TREES, 4 to 18 feet, in great variety; 2000 Prunus Pisardi; 3200 Purple Beech, best dark-leaved variety; 500 London Planes.

5000 FLOWERING SHRUBS in great variety. 12,000 SPECIMEN CONIFERS and EVERGREENS.

1½ to 12 feet high; 2000 Portugal Laurels; 1600 Gold and Silver Variegated Hollies, standards and Pyramids; 2500 Golden Yews, grand plants.

Large quantities of fine Native LARCH, 2 to 4 feet.

Ash, Quick, and other FOREST TREES.

Thousands of FRUIT TREES, including Standard and Pyramid Pears, hundreds of Standard Victoria Plums, grand trees; Standard and Pyramid Damsons, Standard and Pyramid Apples, Black and Red Currants, Whinham's Industry, Keppel, and other popular Gooseberries.

Several hundreds of fine Planting and Fruiting VINES.

Foreign ASPARAGUS

Thousands of TEA and NOISETTE ROSES, in pots, embracing the most popular plants.

Thousands of CLIMBERS, consisting of 100 Clematis Jackmanni, 100 Clematis in variety.

Berberid AUCUBAS, in quantity, and other Stock.

Also 8 two-wheel TRUCKS, and 1 smaller do., suitable for Nurserymen and others.

The Auctioneers desire to call special attention to this highly important Sale. It is the first occasion on which an Auction has been held at these celebrated Nurseries, the necessity now arising solely on account of a portion of the ground having to be given up for building purposes; and the present Sale affords an exceptional opportunity to Noble men, Gentlemen, and others desirous of acquiring large quantities of well-grown Nursery Stock.

Purchasers may arrange with Messrs. Smith & Co. to have their lots lifted and forwarded at the cost of labour incurred and material used. Luncheon provided each day at 11.30.

The Stock may be viewed any day prior to the Sale. Catalogues may be had on the Premises, and of the Auctioneers, Estate Agents, and Valuers, 67 and 68, Cheapside, London, E.C.

It is absolutely necessary that all lovers of first-class gardening should pay our Nurseries a lengthy visit. Our many displays are splendid, and of the highest possible interest.

BEGONIAS (The Editor of *Gardeners' Chronicle* says he opines any further improvement in this flower).

The London Daily Press also says of our last exhibit in London, "Cannell's DOUBLE BEGONIAS rival anything we have seen."

Journal of Horticulture says:—"Cannell's BEGONIAS astonished the visitors."

Medal awarded. CACTUS DAHLIAS, nothing touches them in the world. Our Stock of everything required for high-class Gardening and Prize Winners, particularly seeds, is of the first importance to those who intend to succeed.

VICTOR POTATOS
 (SHARPE'S).

This favourite first early Potato, suitable for any Garden, indispensable for Forcing and Early Borders, and likely to take the first rank amongst first earlyes for market use. Quality and yield all that could be desired. One well-known market grower has this year had a yield of 15 tons per acre on a large acreage. London and Manchester salesmen speak highly of their quality, and report that Victors will keep their bloom and have a fresh appearance after being in the market some days, when other early Potatoes have become discoloured and unsaleable.

The stock we offer is the true yellow-fleshed variety and not the white variety, which is often substituted.

Price per cwt. and ton. State requirements to

OCTOBER.

THE
Gardeners' Chronicle.
 SATURDAY, OCTOBER 8, 1892.

NORMANHURST COURT.

IN view of the fact that the distinguished owner of this beautifully situated place is to preside at the annual dinner of the Gardeners' Benevolent Institution in November, I thought, as I was in the neighbourhood, it might be of some interest if I were to let your readers know what claim Lord Brassey has as a horticulturist and lover of the garden to assume such a position. I was staying at Bexhill-on-Sea, a place I can conscientiously recommend to anyone who wants a quiet and healthful seaside place within two hours of London; the air is delightful, there is a wide expanse of sea, and good bathing facilities. Normanhurst is distant about six or seven miles, and Battle Abbey about two miles further, and probably no greater contrast could be found in all England than that between these two places—the one spick and span with all the appliances of modern civilisation, the other memorable by its age and for the historic memories that are connected with it.

The house itself presents no particular features; the rooms are not large, and it is interesting chiefly from the large collection of curios brought home by the owner of the "Sunbeam" in his voyage round the world. Nearly everybody has heard of the *Voyage of the Sunbeam*, and so everyone who visits Normanhurst is anxious to see the collection, and thus it has been made a show-place; but I have, I must confess, little interest in these things, or in any "show-houses." There is other matter more interesting to me than clubs and spears, corals and vases, and as soon as I could decently do so, I hied me away to the garden, and enquired for Mr. Allen, and found, as I have nearly always done, that in the gardener I was sure to meet courtesy and kindness, and a readiness to impart any information I required. He is a Cornishman. His father lived for fifty years as gardener at Tregothnan (Lord Palmouth's), and an intimate knowledge of that genial and enthusiastic horticulturist, the Hon. and Rev. J. Townsend, Boscawen, at once made us akin, and under his guidance we made a tour of the grounds and gardens. As far as I could judge, the main features of the place are the Conifers and flowering-shrubs. On these the place is made to rely more than on flowers. The place is admirably suited for it; it stands high, embosomed in Oak and Beech woods, with which this part of Sussex abounds. The ground is undulating, thus giving facilities for landscape gardening, which have been carefully made use of. Lord Brassey himself has a keen eye for

the beautiful, and the condition of the grounds and shrubberies show this; the soil being a light and sandy one, seems to suit Conifers exactly. There is no effort at a pinetum, which generally means formality and ugliness, but they are dispersed amongst the woods, and will, in time, add greatly to the beauty of the landscape. I was glad to find that neither Wellingtonias nor Araucarias find favour in his sight. There were a few, but, he holds the opinion (which I have often expressed), that the Wellingtonia will never add to the beauty of our English woods or lawns. When young it is exactly like one of the trees in our children's toy farm-yard, and when it grows older the lower part is bare, and it leaves a head by no means so graceful as our Scotch Fir. Of the Araucaria, he says you can make as good a one out of iron, and in truth this expresses pretty much what one feels about its stiff and formal growth; but there are other Conifers which are just the very reverse of these, and the two which most struck me here were *Cedrus atlantica glauca* and *Abies Albertiana*. It is impossible to exaggerate the beauty of the former; when the sun shines upon it, it is like as if flooded with silver, while the graceful form of the latter, and its delightful fresh colour, makes it a most valuable addition. Then there are *Abies Douglasii*, *Nordmanniana* in considerable numbers, *Pinus*, and the various species of Conifers which have been introduced of late years, and which tend so much to vary our plantations, and are, I think, much more in their place than when dotted singly on a lawn. One of the tennis lawns has a beautiful surrounding of *Rhododendrons*, *Kalmias*, and *Azaleas*, and must be in May and June a very pleasing feature. Of course, alterations and improvements are taking place, and in a few years it will assume a different aspect. The house against which *Ampelopsis Veitchii*, *Ivy*, and other climbers have been planted is now rapidly being covered, and the first signs of its autumn change was showing itself on the *Ampelopsis*, indicating what a glow of brilliant colour will soon envelop it.

Passing away to the walled garden, we were surprised to find what an excellent crop of Pears and Apples there was. There is a long arched trellis work stretching over the middle walk and the two side walks, and although the crop was not a large one, yet there was a better supply than I have seen in many gardens this season, and, I need hardly add, they were all of the best varieties. Mr. Allen was not likely to commit the mistake of planting inferior sorts. This is one of the very few gardens in which I have found a very favourite Pear of mine, *Comte de Lamy*, appreciated. To my mind it is one of the two best October Pears we have, the other being *Doyenné du Comice*. The latter has the advantage of size and appearance, but I do not think there is much to choose between them in point of flavour. Here, also, that best of all early Apples, the Irish Peach, is good, and much valued, and yet I have gone into many a large and small garden, where neither of the fruits named were even known. Peasgood's *Non-such* was in beautiful order, and Mr. Allen showed me a dish of it which he was sending to the Battle Flower Show, and which obtained, I find, as he expected, the first prize.

There were, of course, the usual range of hot-houses, in all of which there was evidence of good management. The Grapes were well coloured, and an even crop all over the houses, not with a sensational bunch here and there, but with a good crop of fairly sized bunches. Of course, as in most places, two varieties gave the

staple supply, Black Hamburgh and Muscat of Alexandria. Others are introduced as matter of curiosity, but the *pièces de resistance* are these two varieties.

But now I come to that which most interested me, as it belongs to my own special department, the cultivation of the Rose; and here Mr. Allen has shown that he can get out of the ordinary rut prevalent in large places. Can anything be more dismal than what we too often see, a rosary so-called, with fantastic arches and such like things too often in a position where it is next to impossible to make them grow. It may be as I saw it in one grand historic place, so overshadowed by huge Elms, that mildew reigned supreme, and there was hardly a flower worth looking at, though as a rule you found old and now obsolete varieties, which most amateurs have long since discarded. Here the rosary was different; it was not large, it was well situated, and the newest and best varieties were grown, many of which such as Mrs. John Laing were in good bloom.

Here, too, I see that universal favourite, William Allen Richardson, occupying such a post of honour as I have never before seen him doing, occupying the entire back wall of a low house, some 25 feet long; here, in the early part of the year it produces thousands of its brilliant-coloured orange-yellow flowers, of which, it appears, there can never be too many, so highly are they appreciated for table and vase decoration; with ladies it is now a great favourite. There is still a small portion of the wall occupied by a *Gloire de Dijon*, but this is doomed, and William Allen will very soon fill up the space.

In another house, in a similar position, I saw another Rose of the same character, quite unknown to me, but certainly deserving of a place for those who desire button-hole Roses. I do not find it in the list of any English Rose-grower; it is called *Madame Ferdinand Jamain*, and is said there to have been raised by Ledechaux. The outer portion of the bud is nearly as deep as William Allen, but there is in the centre a delicate flush of peach, which adds to its beauty, and as it is an equally profuse bloomer, it is quite as valuable, and comes in a little later than the better-known flowers. Mr. Ben Cant was, I am told, much pleased with it, and through him it may yet, probably, find its way into general cultivation. Mr. Allen told me that he obtained it many years ago from the late Mr. Henry Bennett, when he was residing at Shepperton—and he knew what a useful Tea Rose was.

There was also in the same house yet another Rose which was new to me, a very pretty light yellowish Rose, called *Coquette de Lyon*, which are also found very useful for cutting. It is curious how one now and then stumbles on a Rose which has been overlooked in the fierce battle for life, but which some one has "picked up" and cherished.

Here was also an admirably-grown collection of *Chrysanthemums*, consisting of several hundred pots, and a number of other things which we are accustomed to see in a well-ordered garden, but which neither your space nor the profit of your readers will permit me to enumerate. All that I have attempted to do is to show that Lord Brassey takes a decided interest in horticulture, and that in all the surroundings of Normanhurst there are evident proofs of his taste and liberality. I need hardly say that I was received with the utmost courtesy by Mr. Allen, who would have shown me many more things had time permitted. He and his employer have seen the place year by year improving, and they will

have the satisfaction of knowing that each year will add to its beauty.

I think, then, that when Lord Brassey takes the chair at the annual dinner of the Gardeners' Benevolent, he may be hailed as a worthy occupant of it, not only from his high position, but also because he is in the true sense of the word an "English gardener." *Wild Rose*.

NEW OR NOTEWORTHY PLANTS.

PEPEROMIA INQUILINA, HEMSL., sp. n.*

This humble little plant was sent to Kew for a name by Mr. W. Lees, of South View, Oldham, with the following history:—"Whilst selecting some newly-imported pieces of *Odontoglossum Rossii majus* at the Liverpool Horticultural Co.'s Nursery, Garston, near Liverpool, in December, 1890 (I think it was), I came across one piece with the plant, a portion of which I send you, growing amongst the bulbs. The stems were then 1 or 2 inches in height, and growing erect. After having made my purchases, the piece alluded to being amongst the lot, I decided to allow it to remain, embedded as it was, amongst the bulbs, and endeavour to grow it on. I put the *Odontoglossum* and this plant in a wood basket with peat, and it has grown well under the same treatment as the *Odontoglossums*. Some of the shoots are 6 inches long, and those nearest the edge of the basket hang over and grow downward. The basket is hung up in the centre of a span-roofed house close to the glass, and near to the door."

Peperomia is a genus of about 400 described species, but fewer than twenty are enumerated in Nicholson's *Dictionary of Gardening*, though, of course, this is only a selection, and does not include many that have been raised and cultivated in botanic gardens from time to time. A few of the species, such as *P. arifolia*, *P. eburnea*, *P. marmorata*, *P. maculosa*, and *P. Saundersii*, have been cultivated for their ornamental foliage, and are very beautiful objects, though their flowers are exceedingly minute and unattractive.

The present plant does not even possess showy foliage, but, like a small *Selaginella*, it is very pretty creeping amongst Orchids, where it is quite at home. It is a trailing, succulent plant, recalling *Pilea*, but having larger leaves, usually arranged in fours on the slender bright red stems, but there are sometimes three at a joint, sometimes five at a joint, and more rarely only two; they are fleshy, orbicular, or obovate, borne on very short stalks, and rarely more than a quarter of an inch across. The flowers, as in the genus generally, have neither calyx nor corolla; each one consisting of two stamens and an ovary, sheltered by a peltate scale or bract. Individually, they are undistinguishable without the aid of a magnifying glass, and are crowded into tail-like, short-stalked spikes about an inch long, terminating the branchlets.

In so large a genus it is difficult, even with considerable research, and a rich herbarium for reference, to determine whether a species has been described; and it is possible that this one may have been previously described, though I have failed to identify it with any described species. In the Kew Herbarium are specimens of the same species from various localities in Mexico and Guatemala. Some of them have been referred to the widely-spread *P. reflexa*, and some to other allied species. To complete its history, and furnish data for its identification, I may record the localities where this plant has been found and the names of the collectors: Wartenberg, near Tantoyuca, Huasteca, Mexico, collected by L. C. Ervendberg in 1858, and forming No. 358 of his

* *Peperomia inquilina*, Hemsl., nova species.—Species ex affinitate *P. reflexa* sed multo gracilior, caulis repentibus ad nodos radicanibus. Planta glabra, multicaulis, procumbens; caulis carnosus tenerimis rubentibus. Folia breviter petiolata, sessisime quaterna, interdum ternata vel quina, rarius bina, carnosae, evenia, orbicularia vel obovata, circiter tres lineas diametro, interdum emarginata. Spicis terminatis, cum pedunculo 1-1½ poll. longis. Bractea peltata. Stigma fere sessile, terminale. Bacca oblonga, minima.

collection; Valley of Cordova, Mexico, Bourgeau, No. 1805; Colipa, Mexico, Liehmann, 125; region of San Luis Potosi, Mexico, Parry and Palmer, 801; Volcan de Fuego, Guatemala, collected by O. Salvin. I have given this plant the name *P. inquilina*, because it has sprung up in a foreign country, and because it is difficult to find suitable specific names in so large a genus. *W. Botting Hemsley.*

VARIEGATED HOP.

Mr. F. ROEMER, of Quedlinburg, sends us leaves of the Japanese Hop, *Humulus japonicus*, beautifully blotched and variegated with silvery-white. So

THE DOUBLE-FLOWERED TUBEROUS BEGONIA.

I REMARKED at p. 366 in the previous volume of the *Gardeners' Chronicle* that the form of the double-flowered Begonias was open to improvement, my comments thereon being founded upon what I had seen at the exhibitions in London during the past season, and especially the varieties exhibited at the special Begonia exhibition and conference held at Chiswick in August last. I stated that both the firms of Messrs. John Laing & Sons and Messrs. Henry Cannell & Sons had been successful in obtaining the right type of double flower, which in

should be able to build up something else on the ruin he has made. No one knows better what a Begonia or other florist's flower ought to be than Mr. John Laing, the senior partner in the firm of Messrs. Laing & Sons. He had read my remarks in the *Gardeners' Chronicle*, and forthwith sent a boxful of most exquisitely beautiful Begonia flowers. They are perfectly double, and not one of them with anything approaching to even a double centre. I have no hesitation in saying that they are the furthest advance yet made in the production of a double Begonia. The flowers were not large, but they are quite big enough; surely it is a grave error to go in the direction of mere size in a garden flower

FIG. 69.—VARIEGATED HOP: HARDY CLIMBING PLANT.

attractive were the leaves, that we placed one of them in the hands of our artist, who has given a faithful representation at fig. 69. Since then Mr. Roemer has sent us a photograph of the plant clothing a tall pole, and forming a column of densely-packed vigorous foliage, which shows that it is an admirable decorative plant as hardy as the common Hop, and well suited for covering fences, rustic arches, and the like. Mr. Roemer tells us that about 80 per cent. come true from seed.

form should as nearly as possible resemble the double red *Camellia imbricata*, or the double white. The old varieties with several centres should become things of the past, and the flowers of the future must be upon the lines of the old florists. It is easy enough to make fun of our florist-fathers, and to put down their standard of excellence as arbitrary, and the form of the flowers as formal, artificial, and inartistic. Those who do this should find something else to put in their place. He who pulls down

The "6-inch" Begonias got up by square and rule may well be allowed to pass into the limbo of forgetfulness. The largest of the flowers sent by Mr. Laing were 4 inches in diameter, which would give a circumference of over a foot; the smallest were 2½ inches across, the greater number being about 3 inches. There were no names attached to any of them; they were sent merely to show the general quality of the flowers, and the colour leaves nothing to be desired. There were rosy-red flowers, orange-

red, rosy-blush, clear yellow, bright rose, scarlet white, and one a lovely rich salmon colour. If I may be allowed to refer to the Begonia Conference in this place, held at Chiswick, August 23, it would be to the effect that, so far as the competition amongst gardeners and amateurs is concerned, it was something like a failure. Besides the prizes offered by the Royal Horticultural Society, the Turner trustees offered two valuable silver cups, one for double-flowered Begonias, and a similar one for single-flowered varieties. The result being one exhibit only in the class for double-flowered varieties, and none at all in the class for those with single flowers. The council have for two seasons offered numerous Silver-gift, Silver, and Bronze Medals, besides money prizes to be competed for by amateurs, and the response has been very unsatisfactory. Few exhibitors have come forward to compete for the prizes, and the productions have generally been very inferior. Amateurs evidently do not appreciate the work of the society in this direction, or it may be that sufficient publicity has not been given to the fact that these prizes are offered during the season. *J. Douglas.*

VALONEA.

A WORD OF WARNING.

"A FORMIDABLE danger threatens the production of Valonea in this part of Asiatic Turkey. Some twenty years ago the Valonea Oaks in the neighbourhood of Koumkalé, near the western mouth of the Hellespont, were invaded by swarms of caterpillars, which ate off the leaves in the early spring, depriving the branches and fruit of the shade necessary to their vitality during the hot and rainless months of summer. For many years the pest was confined to the small and isolated groves in which it originated. But, during the last four years, it has extended its ravages annually, and now it is prevalent in all the Valonea groves of the plains watered by the Scamaader, as well as in those belonging to Gheikli on the south, and Renkeni on the north.

The injury done to trees is serious, and has already considerably diminished the yield of Valonea in the infested region. In the first, second, and third year of the visitation, the trees continue to bear fruit, though in reduced quantity and shrunken in size. After the third year, bereft persistently of their foliage and with weakened vitality, they cease to bear, and in the course of a few more summers succumb to the annual infliction and die.

No organised measures for the extermination of this destructive invader has yet been set on foot. Here and there owners of Valonea groves have been in the habit of clearing their trees of the spores [eggs] of the butterfly. This is done in the autumn or early winter, and, where practised, has been found fairly efficacious. But the few energetic proprietors who wage war against the foe are sadly handicapped by the immovable apathy of their neighbours, who, shrinking from the impiety of resisting what they deem to be a visitation of Providence, will not stir a finger to rid themselves of the pest. The caterpillars bred on the trees that have been left uncleansed of the spores. After denuding their native trees, they crawl off to the trees of the man who has been at the trouble and expense of clearing them of spores, and make havoc of them also.

The evil, unless soon eradicated, will spread to all the Valonea-yielding provinces of Asia Minor, and seriously diminish one of the staple products of the Turkish soil. The danger to the prosperity of the population thus threatened is sufficiently alarming to call for the active intervention of the State. What is required, is an organised plan of campaign, such as is adopted in the case of an invasion of locusts. The extermination of the caterpillar could be, however, much easier than is that of the locust. The spores [eggs] deposited by the parent moth are attached, in a soft, friable envelope, to the trunk and lower branches of the trees, chiefly on the south side of the trunk and the underpart of the branches, where they find shelter from the frosts and rains of winter.

They can be easily detached with the finger, and that is all that is necessary to insure their destruction. But the work must be done not later than December, so that the detached spores may undergo a thorough and protracted soaking and freezing.

Every proprietor of Valonea Oaks should be compelled, under penalty of a severe fine, to get his trees cleansed by a given date—say December 15 to 27.

By the adoption of some such plan the pest might speedily be made to disappear, and now is the time for the Department of Agriculture to look into this serious matter.—F. R. J. CALVERT, Thymbra, September 12." From the "Levant Herald."

DELROW, ALDENHAM, NEAR WATFORD.

THE property of John Larkin, Esq., with its fine house (the older portion of which was built in 1669), surrounded by some hundred or so acres, bears evidence in its gardens and grounds that the love of gardening dates back to its earliest habitation; as witness the gigantic Wych Elms, the noble Cedar of Lebanon, Beeches, and other trees. The plantings of more recent date still carry us back many years, for it must have taken a long period of time for the fine Conifers to have attained the size they now exhibit. Among them are *Sequoia gigantea* some 40 feet in height, some very old *Libocedrus decurrens*, the beautiful blue-tinted *Abies pungens* about 20 feet high, and other fine species, which must have been rare indeed at the time of planting. Situate as it is on high ground, and in a well-wooded district, devoted principally to agriculture, Delrow is a model homestead, and its garden a very interesting one.

Near the house are some pretty and bright borders and beds of flowers, and passing under the stately trees whose high trunks and various shapes are beautiful objects, we come to a pretty dell, one of a row of three, which might possibly have suggested the name of the place in times gone by, and we pass up the fine shady walk, bounded on one side by a thick *Thuja* hedge, and which is pleasant in summer and a sheltered retreat in winter. On one side is a part of the garden, which was probably planted as the beginning of a Pinetum, for all the specimens—many of them very large and handsome—are Conifers; and this part of the gardens has a distinct character of its own, being shut in by a belt of tall Elms. For the *Araucaria imbricata*, the Junipers, and a few others, the situation may be rather too shady; but the Pines, and indeed, most of the species have thriven well, and emit a most delightful odour, which renders this nook a specially attractive spot. Farther on is another garden in a nook with circular Rose-bed in the centre, surrounded by beds of Carnations, Stocks, and other sweet-smelling flowers, while the borders are of mixed perennials. And in various ways, which are all the more pleasing, for that the conventional customs are not followed, but rather that the ideas of the owner and his wife should be wrought out, are pretty nooks and garden scenes devised.

THE PLANT-HOUSES

are devoted chiefly to Orchids, and in the old block the borders outside the houses are pretty with hardy flowers. The first, a span *Odontoglossum*-house, is filled for the greater part with healthy specimens of *O. Alexandræ*, of which a few good forms are in bloom. A few *Masdevallias* also are in flower, also the pretty *Promenæa xanthina*, and other species, and all are in a thriving condition. Specially noteworthy is the vigour of the various plants of the *Oncidium crispum*, *O. pre-textum*, *O. Forbesii*, *O. Marshallianum*, and others of that section, of which the beautiful *Oncidium Larkiniannum*, which was awarded a First-class Certificate at the Royal Horticultural Society, is one of the most beautiful. This section of *Oncidium* is sometimes killed wholesale by being grown in heat, but here in a cool airy house, the various species of which it is composed, thrive; and the same remarks apply to *Oncidium varicosum*, which here flowers profusely and without the strength of the plants being

diminished thereby. The centre bed of the house is filled with ornamental plants with *Cologyne cristata*, *Cypripediums*, &c., intermingled. The intermediate-house has some fine *Cattleyas*, many, even large specimens, being suspended from the roof, and evidently like the treatment. Some of the "old autumn-flowering labiate" have three sheaths with spikes showing up, and they will be handsome objects soon; the plants of *C. Warszewiczii*, too, and the other species are in fine health. A very handsome *Laelia pumila præstans*, *Cypripedium* × *T. B. Haywood*, *C. Schlimii* and *C. S. album*, the former with seven spikes of flowers, which never seem to fail, for as one goes off another comes on; and other things are in bloom. Continuing the range are two vineries, which are also used for resting *Dendrobium*s, &c. Passing by the covered way clad with *Roses*, *Clematis*, *Honeysuckles*, &c., we get to the fine old kitchen garden (which also encloses the fruit houses), and in which the new block of Orchid-houses has been begun, a commodious span-roofed *Odontoglossum*-house, and a warm house, having already been nearly completed by Messrs. J. Weeks & Co., of Chelsea.

Mr. Larkin is truly fond of his garden, and progress is being continually made in it, Orchids especially being favourites.

THE GENUS GALEANDRA.

SEVERAL times recently I have had occasion to look up the cultivated species of this interesting little genus, and on the last one I made the discovery that the plant so long known in gardens as *Galeandra Baueri* is not Lindley's plant of that name, and that the early history of the genus is in some deal of confusion. It may, therefore, be of interest to place my notes on record, especially as several of the cultivated species are rather difficult to discriminate satisfactorily.

Galeandra Baueri is the original species of the genus, which was described about 1830, from a dried specimen collected by Martin in French Guiana. The original specimen is preserved in Dr. Lindley's Herbarium. Soon afterwards a plant was figured under the same name by Mr. Bateman in his *Orchidaceæ of Mexico and Guatemala*, t. 19, which flowered in the collection of Mr. Barker, and which was obtained by that gentleman's collector, Ross, in 1838, in the neighbourhood of Oaxaca in Mexico. Mr. Bateman points out that this is 1000 miles away from where *G. Baueri* was obtained, but does not appear to have noticed that it was quite a different species; yet such is indeed the case. The original *G. Baueri* has a slender fusiform pseudobulb, and a pale-coloured lip, while *G. Batemanii* has a short ovoid pseudobulb, and a dull purple lip. It should also be pointed out that part of another plant has in some way crept into Mr. Bateman's figure (and also that of Puydt, which is copied from it). Each of the new growths is represented as arising from a stout fusiform old pseudobulb, quite different from the normal ones of this species, and it is quite evident that these old pseudobulbs have crept into the drawing by some mistake. The same plant was also correctly figured in the *Botanical Register* in 1840. Thus, the name became transferred to the Mexican plant, while the Guiana one, not being in cultivation, was forgotten. So much so was this the case, that when Messrs. Loddiges flowered a plant which they had obtained from French Guiana in 1840, it was described by Lindley in 1844 as a new species, under the name of *G. cristata*, yet I cannot distinguish it from the original *G. Baueri*, and Lindley left a note in his *Herbarium*, dated October, 1860, that "*G. Baueri* is certainly the same as *cristata*." Again, in 1853, a plant which flowered at Syon House, was figured in the *Botanical Magazine*; but, in order to distinguish it from the purple-flowered form, it was called *G. Baueri* variety "*floribus luteis*." The habitat is not recorded, but the plant appears to be identical with the original *G. Baueri*, and quite different from the Mexican plant, to which the name had been erroneously transferred. It is remarkable how long

an error of this kind will sometimes remain undetected, but where there can be no doubt about the matter, as in the present instance, the only possible course is to restore the name to the original species. The Mexican plant, therefore, requires a new name, and I propose to call it *G. Batemanii*, which is highly appropriate to a plant from this particular region, which Mr. Bateman, who is happily still amongst us, made his own special study upwards of half a century ago.

G. Devoniana, the largest and handsomest species of the genus, first flowered with Messrs. Loddiges, of Hackney, in May, 1840. It was introduced by Schomburgk from the Rio Negro, a tributary of the Amazon, where it grows both on the stems of

was introduced by Messrs. Veitch, and flowered at about the same date. It has a tuft of hairs on the disc of the lip.

G. minax was described in 1874, from the collection of A. Sillem, Esq., of Sydenham. It is closely allied to *G. dives*. Its habitat is not recorded.

G. nivalis (fig. 70) is another closely-allied plant of unknown origin, which flowered in the collection of Sir Trevor Lawrence, in 1882.

G. Harveyana, which was described in 1883, from the collection of E. Harvey, Esq., of Aigburth, near Liverpool, is allied to *G. Stangeana*, and like it has a tuft of hairs on the disc of the lip. Its native country is not stated.

G. Descagnolleana is a Brazilian species, described

Mex. et Guat., t. 19 (not of Lindl.); *Bot. Reg.*, xxvi., t. 49; *Pact. Mag. Bot.*, xiv., p. 49, cum ic.; Warn. & Will., *Orch. Alb.*, vi., t. 267; Puydt., *Orch.*, pp. 196, 197, fig. 192.—Mexico and Central America.

G. Baueri, Batem. = *G. Batemanii*.

3. *G. Baueri*, Lindl. in *Bauer Ill. Orch.*, Gen., t. 8; Lindl. *Gen. & Sp. Orch.*, p. 187; *Bot. Mag.*, t. 4701 (var. *floribus luteis*). *G. cristata*, Lindl. *Bot. Reg.*, xxx., *Misc.* p. 72.—Guiana.

G. cristata, Lindl. = *G. Baneri*.

4. *G. Descagnolleana*, Rehb. f. in *Ill. Hort.*, xxxiv. (1887), p. 63, t. 22.—Amazon district.

5. *G. Devoniana*, Schomb. ex Lindl. *Sert.*, t. 37; *Pact. Mag. Bot.*, viii., p. 145, cum ic.; *Bot. Mag.*, t. 4610; Maund. *Bot.*, v., t. 231; Lem. *Jard. Fleur.*,

FIG. 70.—GALEANDRA NIVALIS: SEGMENTS, OLIVE BROWN; LIP WHITE, WITH A PURPLE BLOTCH.

Mauritia aculeata and on the ground. The discoverer speaks highly of its beauty, and records clumps of it from 5 to 6 feet high and 3 to 4 in diameter. It was also met with by Spruce and Wallace in the same region, and by Bungeoth in Venezuela, where it is said to grow on *Leopoldinia pulchra*.

G. dives is a native of New Granada, and was described in 1854. It is very near to *G. Baneri*; indeed, Reichenbach afterwards united *G. cristata* with it, which would make them identical. *G. dives*, however, has somewhat smaller flowers, and its identity with the Guiana plant seems doubtful.

G. Stangeana is a species from the Amazon district, which flowered in Consul Schiller's celebrated collection in 1856. I believe it is not now in cultivation.

G. barbata is another Amazonian species, which

in 1887, which was discovered by Mr. Edward Rand, of Paris, and flowered with Messrs. Linden, of Brussels. It is rather near to *G. nivalis*.

G. flaveola appeared about the same time with Messrs. Linden, and is a Venezuelan species introduced by Bungeoth.

Several others have been described, more especially from Brazil, but they are not known in cultivation, and several of them I have not seen. In all probability some of them will prove not to be distinct when a better series of specimens is known.

The following is a list of the cultivated species, with references to descriptions and figures:—

1. *Galeandra barbata*, Lem. in *Ill. Hort.*, iii. (1856), *Misc.*, pp. 86, 89; *Ill.*, vii., t. 248.—Amazon district.

2. *G. Batemanii*, Rolfe; *G. Baueri*, Batem. *Orch.*

ii., p. 195; *Ill. Hort.*, xxi., p. 110, t. 176; Warn. *Sel. Orch.*, ser. i., t. 37; Burnett *Pl. Util.*, ii., t. 63a; *Lindenia*, ii., p. 67, t. 80 (var. *Delphina*).—Amazon district and Venezuela.

6. *G. dives*, Rehb. f. et Warscew. in *Bonplandia*, ii. (1854), p. 98; *Id.*, iv., p. 323.—New Granada.

7. *G. flaveola*, Rehb. f. in *Gard. Chron.*, 1887, pt. i., p. 512; *Lindenia*, ii., p. 87, t. 90.—Venezuela.

8. *G. Harveyana*, Rehb. f. in *Gard. Chron.*, 1883, pt. ii., p. 716.—Origin unrecorded.

9. *G. minax*, Rehb. f. in *Gard. Chron.*, 1874, pt. i., p. 786.—Origin unrecorded.

10. *G. nivalis*, Hort., *Gard. Chron.*, 1882, pt. i., pp. 536, 537, fig. 85 [repeated at fig. 70]; *Ill. Hort.*, xxxii., p. 63, t. 555.—Origin unrecorded.

11. *G. Stangeana*, Rehb. f. in *Bonplandia*, iv., p. 323.—Amazon district. *R. A. Rolfe*.

NURSERY NOTES.

MESSRS. J. CHEAL & SONS'.

ONE of the most promising of the more modern nursery firms is that owned and conducted by Messrs. J. Cheal & Sons, Lowfield, Crawley, Sussex. The extent of land under cultivation as a nursery is at the present time about 80 acres, and most of this considerable area is planted with saleable stock, consisting of fruit trees, ornamental trees and shrubs, and single Dahlias, the latter a speciality of the firm, which is being much worked up at the present time.

The houses, not many in number, are clustered round the nursery offices, and have been erected at odd times during the last twenty years, as occasion for them arose. One of these houses, of span-roof form, contains a collection of Pear trees, treated as single cordons, and trained to wires fixed about 2½ feet apart, running from wall-plate to apex. Some of these are continental varieties on trial, and most of the trees were carrying good numbers of fine unblemished fruits. We noted a new variety, Duchess de Monchy, an excellent late Pear, lasting in good condition till the month of March; Charles Cogoe, a fairly good late variety, and valuable in that way; Rivers' Princess, resembling a Louise Bonne of Jersey, from which it originated—it is very heavy for its size. Belle William is a new French Pear, large, and oblong—a striking fruit; the much-belauded Kieffer Pear, which is thought little of here, either when grown, as are these, under glass, or in the open air. Other varieties remarked were Grosse Callebasse, Durondeau, Pitmaston Duchesse, Soldat Laboureur, Benrre Fulvie, B. Alexander Lucas (an excellent Pear), Conseiller de la Cour, Glout Moreceau, Doyenné Boussoch, Belle de Bruxelles, General Todleben, Chaumontelle, King Edward (a fine stewart), Jersey Gratioli, Beurré Superfin, and B. Sterckmann. This Pear-house gives an impression of a similar one being of great utility in exposed gardens, or those situated in cold, unkindly parts of the country. Most of the trees are planted out, and although as such the crop is larger than what would be afforded by pot-trees, the latter would be more generally preferred, as their removal when at rest would allow of the house being utilised in other ways in the late autumn and winter.

Chrysanthemums occupied a span-house—good thrifty stuff. The propagation of Pelargoniums was proceeding in another, and mixed decorative plants filled a third. An excellent houseful of planting and fruiting Vines was observed, which were awaiting their removal to the south side of a tall Beech hedge to ripen their canes.

The greatest floral novelty of the nursery is a dwarf variety of single-flowered Dahlia, whose height, flower-stalks, blooms, and all, is about 12 inches. These are most floriferous plants, and have, in most instances, what may be termed a spreading habit, with foliage commensurate with their stature.

Unfortunately, the first sharp frost of the season had greatly disfigured them, and we could not distinguish the colours, but were assured that in every point they were the equals, as regarded brilliancy of colour, of their taller sisters. Of course, a rigid course of selection will improve form of flower and habit of growth. In dwarfness there is nothing further to look for, and they may become in time the rivals of the zonal Pelargonium, tuberous-rooted Begonias and other plants used as bedders.

The Pear-arcade, sometimes a picture of fruitfulness, was this season without a fruit; and the fence of oblique cordons was nearly as bare of fruits.

Much of the land is divided into parallelograms, with great hedges of Beech, Mirobalana Plum, or Hornbeam, which afford abundant shelter from, without actually stopping the wind. A large number of hush Apples in a bearing state were remarked, these furnishing much of the fine fruit that the firm sends to various exhibitions, and also samples for the guidance of customers. Not every

variety was carrying a crop; some, indeed, were bare, but the number of these last were few, and sufficient fruit was hanging on the bushes generally to show the characteristics of the varieties. We observed Colonel Vaughan, a good cropper, like Worcester Pearmain, but smaller, and less good in flavour—a fine costermonger's variety; Ecklinville Seedling, a variety that crops well and regularly—the fruits were very fine; Emperor Alexander, good as a bush; Golden Spire, early and good, was breaking down under the weight of its crop; Frogmore Prolific, a capital large fruit, and a good thrifty grower; Cospatrick is another excellent culinary Apple that was bearing well; Wealthy is a showy American variety, of large size; Scarlet Nonpareil was fruiting well, as were Hornead Pearmain, Lane's Prince Albert, Potts' Seedling, Stirling Castle, Lady Henniker, and Sturmer Pippin.

In other quarters, Schoolmaster and the following were fruiting well on little trees two years from the bud, viz., Queen, Peasgood's Nonsuch, splendidly on Paradise; Newton Wonder, Wellington, Blenheim Orange Pippin, Tower of Glamis, full of fine fruit; Swedish Reinette, a variety that crops always well, fruit brightly coloured, with a fine grey bloom upon it; Bramley's Seedling, Cox's Orange Pippin, King of Pippins, and Bismarck, the coming Apple. Of this last there are breaks full of maiden trees—a capital sample; it is naturally short-jointed, which means, barring accidents, heavy crops of fruit.

Crabs of many varieties are grown, and largely the Dartmouth, a very showy crab, purplish-crimson, with a beautiful Plum-like bloom on it; and Transcendent, a glowing American Crab. Next in point of beauty, and exceeding them in numbers, were the different species of Crataegus.

Pears filled several large breaks, the stock being of various ages, and although all appeared to be clean short-jointed vigorous plants, we looked in vain for fruits. In this part the spring frost was very severe, and Pear blossoms succumbed universally in the open land.

Plums, Cherries, Peaches, and all kinds of fruit are extensively and well grown. In the fruit-room, specimens of the following were noted: Worcester Pearmain, Duchess of Oldenburg, a good early Apple, bearing regularly and heavily on stiff loams; The Queen, Yorkshire Beauty, an Apple with a multitude of synonyms—it is a regular and heavy bearer, and the fruits keep till January; Professor, an early heavy cropping culinary Apple; Evagil, Golden Spire, Loddington, Alfriston, and Cellini, an Apple not to be depended upon on heavy land.

Ornamental trees, chiefly Conifers, and evergreen shrubs in large variety, form a large portion of the nursery stock, and Messrs. Cheal, being nearly always engaged in landscape work, and the renovation of gardens, make heavy demands on this. We were therefore not surprised to find much that was worthy of the notice of the planter for effect; and regular transplantation being the rule here, the trees and shrubs were neat, symmetrical, compact, just such as one would gladly choose for planting, and which, with ordinary care would be sure to succeed. *Abies* Lowiana, *A. cephalonica*, *A. Nordmanniana*, *A. Pinsapo*, *A. Webbiana*, *A. amabilis*, *A. magnifica*, *A. grandis*, and many others, were all to be found here. *Pinus* is, perhaps, less well represented, but neat plants of *P. cembra*, *P. inops*, *P. insignis*, *P. Lambertiana*, *P. pinaster*, *P. strobus*, *P. pinea*, *P. ponderosa*, and other species, were remarked. *Ketinosporas* were found in large numbers, and the same remark applies to *Abies*, *Thuia*, *Taxus*, and *Cupressus*. The nursery is rich in fine *Hollies* in variety; and in deciduous subjects of the best sizes for planting.

Roses occupy a considerable amount of land, and grow with a good deal of vigour in the rather heavy loam.

ROUND LIVERPOOL.

(Continued from p. 412.)

ALLERTON BEECHES, NEAR LIVERPOOL.—The property of Henry Tate, jun., Esq., has at its entrance a stately row of Beeches of great beauty

and huge dimensions, one of the largest measuring nearly 16 feet round the trunk. Age begins to tell on one or two of them, but every care is taken to preserve the lives of the aged giants. Around the pretty dwelling-house, clad at the lower part with climbers, are some neat flower arrangements, which are now, of course, showing the season we have arrived at. The hardy plant garden, with its natural rockery and grotto, over which spread large tufts of the different Saxifrages and other rock plants, shows the advance of winter the least, there being still a good display of flowers on the Phloxes, Helianthemums, Anemone japonica, and other late-flowering plants; but the falling leaf and the crippled bud tell plainly that the season of the outdoor flower is over. But at Allerton Beeches, provision is made for keeping up a supply of flowers in winter, for a house of Tea Roses, a goodly array of Chrysanthemums, some fine specimens of *Eucharis*, a fine lot of *Poinsettias*, and other things, show that Mr. John Edwards, the gardener there, is not unmindful of the dull season to be tided over. But the Orchids are the favourites, both with Mr. Tate and his gardener, and in the new houses built by Mr. John Pitkethley, of Garston, they thrive admirably. The houses themselves are of Pitch Pine, the upper staging and the diagonal trellis-work flooring being of the same material. Both in the manner of giving ventilation, of raising the open staging higher above the close moisture-giving stage in winter, and in the manner of damping down the houses by merely turning a tap, there are new and salutary improvements, which have been, no doubt, of great service in the culture of the plants, and also in raising the new hybrids, which are taken such an interest in by Mr. Edwards, who proudly showed his various young broods. Among them we noted young plants, the result of crossing *Cattleya aurea* and *Lælia crispa*, *C. gigas* *Sanderiana* × *Lælia grandis tenebrosa*, *C. gigas* × *C. Mossiae*, *C. Mossiae* × *Lælia xanthina*, *Cypripedium Rothschildianum* × *bellatulum*, and many other strange crosses, either in plants or yet in the seed capsule.

Of the fine specimens of established Orchids, the entrance-lobby gives a good example of healthy plants, well set with spikes. Among them the compact plants of white and coloured *Lælia anceps* are remarkable for the number of vigorous spikes they are sending up. The plants are grown in pots, but are kept high above the rim, and with but little peat above them. *Odontoglossum grande*, too, is well in bloom, the spikes very stout, and one of them bearing eight flowers. A pretty variety of *Vanda cœrulea*, also, is here, with white sepals and petals, edged and tipped with blue, and with a violet-coloured lip; and *Lælia pumila* *Dayana* and other Orchids in flower are arranged with Palms, &c.

In one division are splendidly-grown *Lælias* and *Cattleyas*, *Miltonia vexillaria*, and *Cypripediums*, many of them home-raised. In another division is intermediate-house Orchids, in fine condition. Suspended at the end are some pans of *Pleione maculata*, which are far in advance of any we remember having seen. The largest bulbs are 6 inches in circumference, and the leaves as large as those usually seen on *Calanthe vestita*. Mr. Edwards says he never dries these off. Formerly he used to do so, with what may be called ordinary success; but seeing that they commenced the new growth as soon as the old was completed, he discontinued the drying off, and the result has been extraordinary, both as to growths and flowers.

Passing through the Vineries to a warm-house, in which the centre bed is furnished with handsome Crotons, &c., we find *Vanda Sanderiana* and *Dendrobium Phalaenopsis Schroderianum* good, a fine and vigorous lot of *Phalaenopsis*, and a remarkable collection of *Cypripediums*, excellently well-grown; some *C. Rothschildianum* having their leaves spreading over 3 feet; a plant of *C. bellatulum*, 2 feet across, and without a blemish, and other rare species equally fine. It is a pleasure to look at such plants, even when not in bloom. Mr. Edwards works hard among them, and they repay his care.

WOOLTON WOOD.

The fine gardens of Holbrook Gaskell, Esq., and especially the collection of Orchids, have always been of great interest, and it is evident that Mr. Gaskell does not mean to let the gardens go down. The houses have all been thoroughly overhauled, and the plants re-arranged, and it may be said that the collection of Orchids never looked better than at the present time. One fine feature of the collection in years gone by, however, is missing, viz., the magnificent plants of *Phalænopsis*, which used to luxuriate in the still moist corner of an inner warm-house, whose entrance was through another house. The partition was removed before Mr. Todd's (the present Gardener's) time; the *Phalænopsis* dwindled and the place thereof knoweth them no more. But under the same roof may now be found a splendid selection of *Cattleyas* and *Lælias*. *Cattleya Gaskelliana* being a favourite, is grown in quantity; the plants of it began to bloom on July 1, and have continued until now, and will still continue to flower, some or other of them. There is great variety of colour in this pretty *Cattleya*, and at Woolton is one of the best of the white forms, but a still further merit, and one which makes even what is called a poor variety acceptable, is its fragrance. The autumn-flowering labiatae too, are much grown here, and are about to flower profusely, for it is as free as the *C. Gaskelliana*; *C. Bowringiana* is represented by several large specimens sending up spikes of great strength, with from twelve to eighteen flowers on each; two forms of *Lælia elegans Schilleriana* are in bloom, the one a very handsome form, and fine specimens of *Lælia purpurata*, &c., are in evidence. In this house is a novel and satisfactory plan of growing *Ouvirandra fenestralis* (*Laticca* plant) exemplified by Mr. Todd. The plant, which is in a large pot, has its head brought through an opening in a framework covered with cream-coloured tiles, such as are sometimes used for flooring. The pot is fastened to the framework, and the whole floated on cork fastened to the bottom of the frame. There are about one hundred leaves on the plant, little and big, and the advantages of Mr. Todd's plan is, that it suits the plant, and the foliage looks to much better advantage when seen just below the surface of the water, and spread over the clean cream-coloured tiles.

The Masdevallia-house is filled with large specimens in perfect health, and here the pretty *Masdevallia Gaskelliana*, with its score or so of handsome flowers, is one of the most attractive at present, although the *M. Harryana* varieties, which each bears fifty or more flowers in their season, are grand objects. Those of the *M. chimæra* section are grown in another cool-house, where they thrive marvellously, many of the *M. bella* and *M. chimæra* being 2 feet to 2 feet 6 inches across; they are grown in baskets, and suspended from the roof. Beneath them are *Odontoglossum crispum*, &c.

In the large stove, with ornamental plants on the centre bed, *Dendrobium Phalænopsis Schroderianum* is thriving well, and is found to be very free to grow and flower; *Cattleya Dowiana* and *C. D. aurea* are good. In another house suspended overhead are some grand masses of white and coloured *Lælia anceps*, which are here grown on rafts or shallow baskets, and they are very fine, and sending up spikes freely. All growers round Liverpool agree that these plants do not want much "stuff" about them, and consequently most of them grow them in shallow baskets; those who do not adopt this plan use small pots, and keep the plants high above the rims. Another house is nearly filled with large healthy masses of *Cœlogyne cristata*. With them are several very fine *Dendrobium Falconeri*. They are grown at the warmer end of the house, and are syringed frequently. In general where we find this plant really fine and safe, it is placed in the houses somewhere where it can feel the influence of the outer air. The house where the *Aërides* and *Vandas* are grown, has also some fine *Cypripediums*, the plants of *C. grande*, *C. Schroderæ*, and others of the green-leaved section, being of gigantic proportions and great vigour;

C. Spicerianum, too, and all the other species are well grown. Here *Peristeria elata* has had five spikes; and a grand mass of *Miltonia Moreliana* on a Tree-Fern stem has fifty flowers. Although imported as one mass, there are two varieties, the upper portion having much darker flowers than the lower.

Suspended over the doorway in one of the intermediate-houses is a plant of the curious and beautiful *Cirrhopetalum ornatissimum*, with its rayed heads of white and crimson flowers, three of the segments curiously decorated with crimson fringe. The *Cirrhopetalum* and *Bulbophyllum* have beauties all their own, which never fail to attract. How is it we see them so seldom in collections? Passing through the vineries, in which are good crops of Grapes, black and white, and in some of which *Dendrobiums* are resting, we go through the Peach and other plant-houses, and note in one of them that the back wall is fitted with wall-tiles planted with *Adiantum cuneatum*. This plan Mr. Todd strongly recommends where Ferns are wanted for cutting, as a supply is got from an otherwise useless part of the house, and the plants in pots consequently saved.

The rock-house, with its tall Tree Ferns and undergrowth of *Todeas* and other Filmy Ferns, and the warm case of tender *Filmies*, are as pretty as ever. The rockery outdoors is well furnished, and in passing a glimpse is obtained of a good lot of *Chrysanthemums*, which prove that Mr. Todd has not quite escaped the *Chrysanthemum* mania, which is just now raging with great violence in many of the gardens round Liverpool.

THE ROSARY.

A PAIR OF CHOICE NOISSETTE ROSES FOR CHRISTMASTIDE.

It may be faicy, but I think it fact, that we enjoy soft yellow or primrose colours the most towards the close of the year. Hence, such charming Noisette Roses as *Celine Forestier* and *Triomphe de Rennes* seem never half so welcome as from September to November. The colours themselves seem to melt into softer shade with the shortening days. As the golden grain is gathered in from the fields, and the sere and yellow leaves of Limes, Sycamores, and Chestnuts begin to fall and the fluffy rich primrose harvest of blossom of the evening Primrose (*Oenothera macrocarpa*), stiffen into huge crops of seeds for future seasons, these and a few other Roses, mellow softer, richer beauty. *Triomphe de Rennes* is probably the most tender of all the Noisettes, not even excepting the very oldest and best of them all, *Lamarque*, so pearly white, and so delicately fragrant. But of these last, no phrases truly describe the odour of *Lamarque's* delicious perfume, or the agreeable scent of *Triomphe de Rennes*.

The flowers have also a perfection of form in bud, and an exquisite finish that few Roses can equal, perhaps none excel. The colour, too—a mustard or canary-yellow—is very rare among Roses. It blooms differently, and hardly so freely as *Celine Forestier*; but one perfect bloom or half-opened bud of *Triomphe de Rennes* is worth two or three of *Celine Forestier*, lovely and most useful and welcome as this latter always is. Nevertheless, it is doubtful if *Triomphe de Rennes* is half as much grown as *Celine*; the chief reason for this is its tenderness. The fact is, both are tender by nature; as most of the Noisette Roses are, they become more tender still through their fostered habits of very late blooming in the open air. Neither are much, if any, more tender than the *Maréchal Niel*, blooming side by side with them under identical conditions of site and soil. *Triomphe de Rennes*, however, may be slightly more tender. But surely all these delicate and choice—I do not include the *Maréchal* in the first adjective—Noisette Roses are worthy of the warmest bit of wall we can give them at any season, and most of all to link these last showers of golden blossom with the first-fruits of the snow on the threshold of winter.

I prefer these and other Noisette Roses on their own roots, because of their tenderness; and under such conditions, though they may often be cut down through cold, they are seldom or never destroyed. The comparative hardness of roots and root-stocks must be seen through a series of years to be believed in. With moderately rich soil on a warm wall, and under wise—that is, a sort of wait upon Nature, and act accordingly—culture, these Roses will live and bloom for years through many months in the year, fading in a sort of climax of beauty at the end, which must please most eyes and win most hearts among rosarians. *D. T. F.*

ROSE SOUVENIR DE LA MALMAISON.

How seldom it is now one meets with this Rose, and yet it is one of the best and most lovely anyone can grow, for it is seldom during the summer and autumn months that it is out of flower; and at this season it has quite a wealth of bloom, the half-expanded buds being beautiful, as not only are they perfect in form, but they have the most delicate shading of flesh colour, and stand boldly up on stout stems. In habit, *Souvenir de la Malmaison* is strong and the plants grow freely, forming quite large bushes if not hard pruned, which they should not be, but only thinned out and just shortened back; and when so treated, and left pretty much to themselves, they blossom freely, and make a very fine show. For beds or masses grown together, they are grand, and a striking effect is produced by planting among them some *Gladiolus brenchleyensis*, which, with their tall spikes of scarlet flowers, contrast well with the pale-coloured Rose. Those who are so fortunate as to have *Souvenir de la Malmaison*, will find this a good time for propagating it, as it strikes freely from cuttings or slips, the latter being preferable on account of having a heel. This part should be trimmed off smoothly, and the slips then inserted in sharp sandy soil under a handlight or frame where they can be kept close and shaded till they root. *J. Sheppard.*

AUTUMN AND SPRING-PLANTING OF ROSES.

The full advantages of early autumn-planting cannot be sufficiently realised by gardeners, or we should find it much more frequently practised. After the plants are a little more than three parts ripened, the sooner they are planted the better will they stand the winter, and thrive the following season. When planted early, Roses make an abundance of new roots that serve the double purpose of making them semi-established, and also supplying the tops with sufficient sap to counteract the effects of drying winds and frost that so often work havoc among newly-planted Roses, more especially if the operation be done later than the early part of the month of November. I have frequently planted at the end of September or early in October, and never regretted doing so in a single instance. Of course, I do not advocate the lifting of plants until they are at least three parts ripe, and during some seasons this is quite a month later than another; nor would I plant Teas and Noisettes so early as the hybrid perpetuals when grown upon the *Manetti* stock. These latter have been ripe enough for transplanting ever since the middle of September. Only a few of the later-growing varieties are still retaining their foliage, while almost all of the Teas are in full leaf and growth. To move these last at the present time (October 1) would be wrong and injurious; but even these are often left much too long, and until they are completely at rest. If I could not transplant reasonably early in the autumn, I would much prefer to leave the operation until March, as I would rather my plants either get settled previous to winter, or else commence slight root-action as soon as put into fresh ground. Planting Roses in the dead of winter has never turned out so well as planting in the early autumn or early in spring. *A. P.*

ROSES IN POTS, AND PLANTED OUT.

A gentleman called upon me the other day, and expressed some surprise on finding that we had been gathering Roses daily up to the last week in September. He was fond of Roses, and complained

that he did not obtain them in the autumn. After some conversation upon some of the details of Rose-growing, I found that we differed on two important points: one was the desirability of transplanting Rose bushes, &c., every second or third year; the other, the selection of varieties. No one can obtain plenty of Roses late in the season from plants out-of-doors, unless the Tea-scented varieties are grown. Hybrid perpetuals do flower in the autumn, but not so freely as the Teas. A great deal also depends upon the method of culture adopted, for, however well the ground be prepared, or carefully the plants are planted, they will not continue to do well unless they are periodically lifted and replanted. Tea-scented Roses succeed admirably even in heavy wet soils if they are budded upon the seedling Briar, which is, I suppose, the best stock for Tea Roses on such soils. The Rose-bed should be raised about 1 foot above the level of the ground, the sides of the bed being banked up in some way; we turf ours over, and the soil being heavy, a good dressing of stable-manure taken from horses, which have stood on a peat-bed, suits the Roses admirably. One-year-old plants were put out, and they made excellent progress for three years; at the end of that time, the entire collection of plants were lifted and replanted in the same bed; but after trenching it to a depth of 2 feet, including the depth of a foot above ground, which had, since it was first made, sunk nearly 6 inches, the retrenching raising it to its original height by the addition of manure and some fresh loam, the loam being necessary in affording the Roses a strong fresh start. The lifting and transplanting should be done not later than the month of November, and when the work is finished, a mulch of dry stable manure in a rotted state should be spread on the surface and around the stems of the plants. This sort of mulch will be found good for all Roses, whether they have been replanted or not, for very severe frost will injure even the more hardy hybrid perpetual Roses if unprotected. The Tea-scented varieties will continue to flower until the frosts stop them; but near the sea, and sheltered from the east and north, blooms of these varieties can be gathered up to the end of the year. In inland places—the neighbourhood of London, for instance—the weather prevents this, cold rain either causing the flower-buds to decay or frost to destroy them.

It is at this period that an airy greenhouse comes in handy to prolong the bloom for a month or two. The Roses for late bloom may be planted out, but it is probably more convenient to grow them in pots, and they should for autumn flowering be rested, as it were, in summer, by being kept comparatively dry at the roots, something in the same way in which they are rested in the Riviera through heat and drought in summer. The Roses there lose their leaves in summer, the hybrid perpetuals first, and the Tea-scented varieties later. About the end of August, or early in September, they are pruned. When the rains come about the end of September, the Roses start into growth, and flower freely until the middle of January, and it is rather remarkable that the later the rains are in coming, the better are the Roses. By imitating the temperature of the Riviera in our glasshouses in November, December, and January, we may succeed in obtaining Roses in our glasshouses. The late Dr. Bennet, who carefully registered the temperature in his garden on the Genoese Riviera for fifteen years, found that the minimum for November was 49° 2', maximum, 60° 1'; December: minimum, 42° 2'; maximum, 55° 1'; January: minimum, 42° 8'; maximum, 53°. January is the coldest month, the temperature rising again in February. The temperatures we can easily have in our houses, but the difficulty comes in with our leaden skies and the fogs; the sun may scarcely be seen for a week, and when it does show itself, "it just blinks a wee and sinks again." All we can do is to place our plants near the glass roof of the house; the atmosphere should be kept well on the dry side; and there ought to be a free circulation of air. It is important that Roses should be kept free from insect-pests and mildew at all times; but in

winter it is well to see that there is no trace of any mildew or green-fly on any of the plants. The Roses should be planted in good loamy soil, and the pots should be well drained. For the Tea Roses, a rather light soil is best; about a third part of light fibrous peat should be added to the yellow loam, and crushed bones which compose the usual compost, and if some pounded charcoal be added, it will aid in keeping the soil porous. They should be afforded water enough to moisten the compost throughout, and should not be watered before the soil is well on the dry side. *J. Douglas.*

COLONIAL NOTES.

PEAS IN JAMAICA.

The *Bulletin of the Botanical Department, Jamaica*, contains an elaborate table on the rate of growth, the time of flowering, and other particulars relating to Peas as grown in Jamaica. A general summary of the tabular matter is given as follows:—On comparing the above figures it will be seen that the varieties that have given the best results are Abundance, Duke of Albany, Champion of England, Carter's Dignity, British Queen, Carter's Supreme, Carter's Telegraph, and Carter's Telephone, the latter not a heavy cropper, but a fine flavoured Pea. Laxton's Alpha and Princess Royal produced the heaviest crops, but the Peas were not so finely flavoured as some of the other kinds. I might add that, with a very few exceptions, all the varieties named are very good; in making selections from the list, intending growers would do well to consult the column giving the heights of the various kinds, and give preference to those of medium height, say 3 to 5 feet. They do not require so much attention in the way of staking as the taller kinds, and are not so likely to be blown down by strong breezes.

THE WEEK'S WORK.

PLANTS UNDER GLASS.

By R. MILNER, Gardener, Penrice Castle, Swansea.

POINSETTIAS that are still growing in pits should now be removed into a warmer structure, for if kept in a low temperature too long they are liable to lose their bottom leaves, which will greatly disfigure the plants. In case a portion of them are required to bloom early, these should be placed at the warmest end of the stove, and at the same time keeping them well up to the glass, where they will quickly come into bloom. The most suitable place for the main stock is a disused Melon or Cucumber-house, where there is plenty of heat at command, and as these structures are generally low, it enables the grower to stage his plants well up to the glass, which is indispensable. Avoid overcrowding as much as possible, and assist them occasionally with clear manure water, which will tend very materially to increase the size of the bracts.

Euphorbia Jacquiniflora.—These plants will require similar treatment to the above, and when well grown form some of the most useful winter-flowering plants we have. As the days shorten, care must be taken to avoid giving too much water at the roots, as these plants are very impatient of such treatment.

Gesneras, if potted on as advised, will be found most useful later on. Keep them free from thrips, &c., by lightly fumigating the plants occasionally, and avoid syringing the plants overhead during any period of their growth, or the foliage will become disfigured. Grow them on a shelf near the glass, so as to encourage a sturdy growth.

Where *Eranthemum* and *Linum trigynum* have been grown in cool pits, they should now be removed to warmer quarters. The latter is very subject to red-spider, which necessitates extra precautions to keep the plants free from this pest.

The *Epiphyllums* are most useful plants for autumn and winter. A few of them may be placed into a warm intermediate house, where they will quickly show bloom.

Winter-flowering Begonias should receive attention. They will be found useful later on. When the pots become well filled with roots, assist them frequently with weak applications of manure water.

Remove *Thysacanthus rutilans* and also *Salvias* from the cool pits or frames into their winter quarters; also *Eupatorium repandum* and *E. Weinmannianum*. Grow the latter in a cool house, well up to the roof glass, where just sufficient heat is at command to keep out frost and damp. These plants will now require plenty of manure water, especially such as are growing in 5-inch pots, as by this time they will be one mass of roots.

Primulas should be given a light and airy position close to the glass, and when well rooted assist them with a little soot water and a pinch of Thomson's Vine and Plant Manure occasionally.

Bouvardias should be given a light position in an intermediate house. Plants which have been growing in pots during the summer will ere this have exhausted their food supply, and should be assisted with applications of weak manure water, or one of the well-tried fertilisers. Any which were planted out in prepared beds and lifted, should be kept in a cool pit, and shaded from bright sun until well established, before taking them inside.

THE KITCHEN GARDEN.

By G. WYTHES, Gardener, Syon House, Brentford.

SAVING AND PROTECTING LATE VEGETABLES.—With the absence of sun, and the shorter days, preparation must be made for the supply of other than green vegetables, and much may be done through this month and part of the month of November to bridge over the period that intervenes before forced vegetables come in more generally. With this in view, pods of French Beans should be gathered whilst tender, and the stalk-end placed in water which has a bit of charcoal in it, changing the water occasionally. Thus treated, they remain for a longer time fit for use than many persons would suppose likely. Marrows, also, keep a considerable time if cut and stored in a cool place. Cardoons will need protection, or lifting with a ball of earth and placing in the cool root-stores, examining them occasionally, and cutting away decaying parts.

CAULIFLOWERS AND BROCCOLI will tide over a considerable period if they are gone over twice weekly, and those with heads the size of a cricket-ball removed intact to frames or outhouses, where they can be protected from frost and rain. Veitch's Protecting Broccoli is now coming in, and it will last till the winter kinds are ready for use. Where this early variety can have garden-frames for its preservation during the next few weeks, the produce will be better; and it is always best flavoured if the plants are lifted before they get of a large size. Remove all decayed foliage before putting them in the store or frames, and plunge the roots in a light moist soil, and admitting air as much as possible in fine weather.

SEAKALE.—Though it is still early for lifting, the crowns may be got ready for forcing by clearing away the decayed foliage and weeds, the exposure to sun and air maturing them for forcing. If very early Seakale is required, it is best to plant a quarter for this purpose in a warm part of the garden, so that the growth may thus be early, and therefore thoroughly matured early in the autumn. It is well to lift a week or ten days before it is required to be put in the forcing-house, an earlier start into growth being the consequence of doing this with less heat. The later forcing crowns should be similarly treated.

TOMATOS.—The plants on walls must now be protected from the chance of injury from frost, and ripening fruits placed on shelves in a cool fruit-house to fully ripen. Here they will keep good for a long time, if not exposed to damp. Shelter may be afforded the plants for a short time with bast mats if fruit is still swelling. Plants in pots for winter use should now be removed to an intermediate-house, airing them freely, and leaving the top ventilators open in mild weather. No time should now be lost in securing a crop by setting all the flowers which open, this being the fruit which will ripen in the winter. Plants raised for spring fruiting should be growing freely, and these, and the seedlings, may require to be shifted, but a large shift should not be given them; nor should the soil be rich, so that the

plants may grow sturdily. The temperature need not at night exceed 55° or by day 70°, and the plants should stand near the glass.

MUSHROOM BEDS, if prepared as advised, will now be coming into bearing, and the temperature should be kept at 50° to 55°, the flavour of Mushrooms being impaired by high temperatures, and the beds get worn out in a short space of time. More material may be got in readiness for succession beds; and the spawning of beds, when these are of a suitable degree of warmth, will demand attention. Never cover a bed with cold soil, but always warm it first. Outside beds will require protection from heavy rains.

THE ORCHID HOUSES.

By H. A. BURDEAR, *Orchid Grower, Highbury, Birmingham.*

NEWLY-IMPORTED ORCHIDS.—Cattleyas and Laelias imported in the autumn or winter should, on being received, be washed clean, potted, or basketed without undue delay, and gradually inured to light, moisture, and warmth, the latter being less than is required by established plants of the same species for some time to come. The conditions of the East India-house will be favourable to their quickly regaining the plumpness that was lost during their transit to this country. The East India-house is not usually recommended for Cattleyas, but it is better to run the risk of a new growth in mid-winter than to attempt to keep the plants dormant until spring; there may, of course, be exceptions to this rule, but I find, generally, that imported Orchids gradually and surely go from bad to worse, until such time as active growth sets in, after which time they surely but slowly recover their health.

PROTECTING THE HOUSES FROM COLD.—Fire-heat being a necessary evil, the truth of which no one can doubt, to do with the least amount of it should be the object of every cultivator, studying at the same time the health of his plants. In very cold weather, when hard firing is a necessity, an impoverishing aridity is the result, although the thermometer may still show a temperature below the proper point. Again, one may notice sometimes plants (especially those near the roof, or standing near the glass ends of the house) which are covered with a heavy dew-like moisture, which is particularly noticeable the first thing in the morning, and which remains on the plants a longer or shorter space of time, and sometimes the whole day; this state of things is not satisfactory, and bodes ill for the plants, it being the result of extremes of heat and cold—on the one hand the excessive heat of the hot-water pipes, and on the other the cold making itself felt on the roof, ends, and sides of the house. A simple and effectual remedy in such case is to employ some kind of protection in cold weather, and this, if not already at hand, should be procured, and held in readiness for use. It may be a garden mat, or piece of sackcloth—anything that will make a difference of from 5° to 10° in the warmth of the house. Many gardeners leave the summer roller-blinds in position for this purpose; but they are, as a rule, far too thin to be of much service. Whatever is chosen as a covering, it should be so arranged as to be handy for laying on and taking off. A good method is to make it so that it will cover the roof from top to bottom in lengths of 8 or 10 feet. Each length will require five strips of wood to be tacked on, of sufficient weight to keep the wind from blowing them off, one piece at each end, and the others at equal distances apart, having the required number of lengths to reach from one end of the roof to the other. They are simply laid on, and unrolled at night, and rolled up the following morning, each length in a small roll, and left lying on the roof till again required for use. On this principle, reed mats are made and used very largely in Belgium. They are neatly tied with twine to five or six strands of thicker string running lengthwise, and although cumbersome to look at when rolled up, they nevertheless answer well as protectors from frost and from strong sunshine. ED.]

FRUITS UNDER GLASS.

By J. RIDDELL, *Gardener, Castle Howard, York.*

POT VINES.—If the canes have begun to attain that dark-brown colour which betokens ripeness, they may be placed against a hedge or wall with a southern aspect, being securely fastened to prevent injury from wind. When drying winds prevail, the soil in the pots quickly parts with its moisture, and it will be necessary to frequently examine the plants to ascertain the condition of the soil. Canes less

well-ripened had better remain in their present quarters, and have the benefit of a little fire-heat applied during the day, and a dry buoyant atmosphere maintained. Stop any growths which may have pushed since they were last trimmed, and if any laterals remain, cut them off. It sometimes, however, happens that a few of the stem leaves fall prematurely, or are broken off by accident, so in cases of this kind the laterals with the leaves nearest the stem had better be allowed to remain, as an aid to full bud development. Fruiting canes may, at this season, be cut back to the desired length. Where due attention has been paid to stopping, little more will now be necessary than to remove the ends close to the second node. By pruning thus early, the wound has time to heal before the plants are again started into growth.

FIGS.—Plants in pots which were early placed out-of-doors will now have lost all their foliage, and may be cleaned if they are infested with scale. For this purpose, we use a stiff brush and Fir-tree Oil at its recommended strength, going over every twig and branch carefully, and making sure of getting at every one of these pests. The dressing should be repeated at intervals of a fortnight or three weeks throughout the winter, and when forcing-time arrives, the plants will be clean to start with. Give the plants the protection of a cool-house before severe weather sets in, and although the soil in their pots should not be allowed to become dry, yet very little water will be necessary while growth is dormant. Plants which have been kept growing to meet a demand for fruit, should on no account be still forced, but allowed to go to rest forthwith, or the first crop of next year will be a small one. Lower the temperature of the house containing them, and admit air freely night and day.

STRAWBERRIES in pots should be placed in a cold frame when frosty weather occurs, and sufficient accommodation of this kind should be reserved for them. It is always desirable to plunge the pots in these frames in coal-ashes, sawdust, hard tree-leaves, &c., to the rims.

THE HARDY FRUIT GARDEN.

By H. MARKHAM, *Gardener, Moreworth Castle, Maidstone.*

GOOSEBERRIES.—These, like other fruits, must have timely attention in the autumn if the best results are expected. The Gooseberry is usually grown as a bush, but if it be planted against north or west walls, and trained fan-fashion, the fruit is equally large and fine, and may be protected by netting from birds, and thus be kept for dessert in fair condition till about this date. A soil that is rather heavy best suits this kind of fruit, and, whether planted as bushes or against walls or fences, the ground, if it will bear it, should be deeply trenched, at any rate, to the depth of 18 inches, breaking up the subsoil, but leaving it in its place. Where Gooseberries have stood for many years, the bushes seldom produce fine fruits. I would advise the grubbing-up of these as fast as new plantations come into bearing. If land is prepared at this season for new plantations, new bushes may be planted at any time during autumn and winter. The bushes may be planted at first somewhat close together, but as they grow and gain in size, they should not be stinted for space, nothing being worse for the Gooseberry than crowding them together, the fruits coming small and poor in flavour. In making plantations, it is advisable to keep late-ripening varieties, and those intended for dessert, apart from those which bear early, or are used in the green state, it being then easier to protect the best and latest. Planting should be done when the soil is moderately dry, making the soil firm about the roots, which can be better performed with dryish soil than that which is wet. Do not bury the roots deeply, certainly not more than 6 inches. If the work be done in the months of October and November, good sized bushes may with care be successfully transplanted without the loss of a crop next year.

PRUNING.—Where there is much fruit grown, the pruning of Gooseberry-bushes may be proceeded with forthwith, even if some of the leaves still hang on the branches. In pruning, freely thin the shoots, and keep the crown of a reasonable size and neatly-shaped; do not let branches or shoots cross each other, and spur back all shoots that are removed to two buds, cutting out whole branches where crowding is likely to occur, and cut away all shoots that hang too near the ground.

BLACK CURRANTS.—The bushes frequently carry too many shoots in the middle of the head—this is a mistake; they should have these freely thinned out like the Gooseberry, so that light may reach the fruits in the middle of the bushes. The young wood should not be shortened in bearing bushes, as it is on such that much of the fruit is borne. Keep the heads shapely, grub up root-suckers that are wide from the main root, and keep the land clean.

NUTS, ETC.—As soon as the husks of Filberts and Cobs get brown, they should be gathered when quite dry. Store them in a fairly dry spot, but not too dry, or kernels will shrivel. Spread them out thinly, and admit air to the place in which they are stored whenever it is favourable for so doing; this will prevent mould attacking them. Freshly-gathered Apples and Pears should be well ventilated at first, and for several weeks after gathering, to get rid of the moisture exuded by the fruit, reducing it in amount as the season advances, and fruit gets drier on the skin.

THE FLOWER GARDEN.

By H. W. WARD, *Gardener, Longford Castle, Salisbury.*

PLANTING BULBS IN GRASS.—In these columns, September 24, p. 371, reference was made to the planting of various kinds of bulbs in the flower-beds then being cleared of the summer bedders. We are now busily engaged planting in masses in the grass, open spaces amongst trees, and alongside of walks, Tulips in variety, Polyanthus Narcissus, mixed Hyacinths, Scillas, Crocuses, &c. We have well-established lines of Snowdrops on either side of the walks, as well as large clumps among the trees, and masses of Daffodils and Bluebells, and additional groups of Hyacinths, Tulips, &c., will, we expect make a good display in the spring, and to this show of bloom masses of Violets and Wall-flowers will add fragrance and variety. The bulbs are planted in holes about 7 inches deep, and covered with fine mould. It is a mode of growing these bulbs which should be more commonly practised, as the cost of the bulbs by the hundred or thousand is very moderate. The same remark applies to the planting of Lilies in open spaces, in bog and other beds. If planted in sunken pots filled with suitable soil, their roots will not be interfered with by those of trees and shrubs. Quantities of the above-mentioned bulbs, together with good-sized patches of Scillas, Chionodoxa, Irises, Colchicum autumnale, Ranunculus in variety, Anemones (double and single), Tritelia uniflora, Crown Imperials, Lilium candidum, and Hepaticas, are now being planted in the herbaceous borders. I prefer to plant these in patches, especially Scillas, Chionodoxa, Crocuses, and such-like. They are all deeply planted with the dibber, and as they are left in the ground after flowering, there is no replanting required. It answers well in our light soil, but it would not be advisable to plant bulbs so deep as we do in heavy soils, that is, deep enough to admit of the ground being forked over without disturbing the bulbs.

CARNATIONS.—Here, I never pot up layered border Carnations, or winter them in cold pits and frames, but plant them direct from the mother plants early in the present month, the ground being previously dressed with very short well-decomposed manure and dug, and well broken down, treading it over evenly, and surface-dressing it with soot and wood-ashes, which are scratched in with a rake when the levelling is done. Soot and wood-ashes protect the plants from their chief enemy, wire-worms, and some kinds of grubs, which feed on the roots. The plants are taken up with nice balls, and planted in rows 1 foot asunder, and at the same distance from plant to plant in the rows, letting them down as low as the "grass," and making the soil firm about them. If a dressing of wood or fine coal ashes be laid on between the plants to the thickness of about 2 inches, frost will not readily reach the roots. Of course the plants are watered as soon as planted, to settle the soil about them.

HARDY FERNERIES.—Examine hardy Ferns, and remove any leaves that may have become disfigured by thrip or other cause, but preserving all others, and pulling up weeds. Thin out the carpet of Ivy and Periwinkles, where these plants have become too thick together. The mixture of the green, bronze, and yellow fronds of the Fern are very effective and seasonable now.

EDITORIAL NOTICES.

LETTERS FOR PUBLICATION.—All communications intended for publication, as well as specimens and plants for naming, should be addressed to the Editor, 41, Wellington Street, Covent Garden, London. Communications should be WRITTEN ON ONE SIDE ONLY OF THE PAPER, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

NEWSPAPERS.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

Advertisements should not be sent to the Editor, but to the Publisher.

APPOINTMENTS FOR THE ENSUING WEEK.

MEETINGS.

WEDNESDAY, OCT. 12. { Conference of the National Chrysanthemum Society at 7 o'clock.

THURSDAY, OCT. 13. { Brighton and Hove Chrysanthemum Society.

SHOW.

WEDNESDAY, OCT. 12. { Exhibition of October-flowering Chrysanthemums, at the Royal Aquarium (three days).

SALES.

MONDAY, OCT. 10. { Great Sale of exceptionally well-grown Nursery Stock, at the Woking Nurseries, Woking, by Protheroe & Morris (five days).
Dutch Bulbs, at Protheroe & Morris' Rooms.

Plants from Belgium, at Protheroe & Morris' Rooms.
Lilies and Dutch Bulbs, at Stevens' Rooms.

TUESDAY, OCT. 11. { Orchids, from Messrs. F. Horner, & Co., at Protheroe & Morris' Rooms.
Dutch Bulbs, at Protheroe & Morris' Rooms.

WEDNESDAY, OCT. 12. { Sale of Rhododendrons at Matlock Moor, by Protheroe & Morris.
Dutch Bulbs, at Protheroe & Morris' Rooms.
Lilies and Dutch Bulbs, at Stevens' Rooms.

THURSDAY, OCT. 13. { Dutch Bulbs, at Protheroe & Morris' Rooms.
Plants from Belgium, at Protheroe & Morris' Rooms.
Lilies and Dutch Bulbs, at Stevens' Rooms.

FRIDAY, OCT. 14. { Orchids, from Messrs. Charlesworth, Shuttleworth & Co., at Protheroe & Morris' Rooms.
Dutch Bulbs, at Protheroe & Morris' Rooms.

SATURDAY, OCT. 15. { Dutch Bulbs, at Protheroe & Morris' Rooms.
Dutch Bulbs and Lilies, at Stevens' Rooms.

CORRECTED AVERAGE TEMPERATURE FOR THE ENSUING WEEK, DEDUCED FROM THE OBSERVATIONS OF FORTY-THREE YEARS, AT CHISWICK.—51°·7

Horticultural Literature.

WE had occasion in our Jubilee numbers to pass in review the progress of horticulture during the fifty years existence of this Journal. Incidentally we had, of course, to note the horticultural literature of the period. We are reminded of the same subject by the publication of Mr. WILLIAM PAUL'S *Contributions to Horticultural Literature*,* which extend over the same space of time. Mr. PAUL, though an active and successful man of business, has, throughout his career, recognised that he had duties to his profession, independently of any personal advantage that he might derive from it. A keen observer and a clear thinker, he has, so far as the exigencies of business allowed, availed himself of the splendid opportunities at his disposition, and powerfully contributed to the advance of horticulture and the profit of its devotees. Turning over the pages of his book,

* *Contributions to Horticultural Literature*, being a selection of articles written for gardening periodicals, and papers read before various Societies from 1843 to 1892, by WILLIAM PAUL, F.L.S. (WILLIAM PAUL & SON, Waltham Cross, Herts, 8vo, pp. 565).

and remembering the characteristics of its author, we can but feel that it has been a distinct loss to science that commerce should have been allowed to sway his destinies. Those who examine this volume will, we think, agree with us in this opinion. Be this as it may, Mr. PAUL has achieved success and renown, and he can look back to a half-century's progress, and use with pride, though from exactly opposite reasons, the words of ÆNEAS, "et quorum pars magna fui."

The book is dedicated to the author's life-long friend, Dr. HOGG, and its contents are roughly classed under three headings: 1, Roses; 2, Trees and Plants; 3, Fruit-culture and Miscellanea. On most of these subjects, Mr. PAUL has written largely and often, so that, so far from considering the present selection as representing a small number of articles, as the author seems to think the public will do, we are surprised that a business-man should have been able to devote as much time to horticultural literature. Moreover, we hope Mr. PAUL will forgive us if we say that his book would have been even more valuable if the matter had been as carefully "rogued" as his own seed-beds are, and if some portions that were of transient or personal importance only, had been pruned-back hard.

The first article, "Roses in Pots," reminds us that in 1843 these were novelties, and that some of Mr. PAUL'S greatest triumphs have been achieved in their culture, and that not the least valuable of his many books is that on *Roses in Pots*, now in a seventh edition. It is curious to see in the list of kinds recommended in 1843 for this purpose, scarcely a single variety that is now in existence. Amongst those mentioned at that early date, which still hold a foremost place, are *Devoniensis*, *Madame Bosanquet*, and *Niphetos*. The historical data supplied by Mr. PAUL, indeed, constitute one of the most interesting and important features of his book. How odd it seems, for instance, to be told that the *Rosa berberidifolia* var. *Hardii* should at that time have been root-grafted on to the *Mahonia*. No wonder Mr. PAUL says it was not likely to thrive for any length of time on a stock of so very different a character.

The lecture on the history and cultivation of the Rose will be useful to those who are puzzled to remember the origin of hybrid Chinese and hybrid perpetuals, and other sections of cultivated Roses. It is interesting from this point of view to compare the lecture given in 1845 with that read at the Rose Conference at Chiswick in 1889. In both these papers we find evidence of the scientific spirit we have before alluded to, thus: "The raiser of seedlings should endeavour to break new ground, strike out new combinations by bringing the hitherto uncultivated species into his arrangements;" and, again, in an article in the *Gardeners' Magazine* as recently as July 2, 1892, we find, "before commencing work" [raising seedling Roses] "we ought to have a pre-arranged plan—some definite object or objects in view—and work for their achievement." But Mr. PAUL has not only scientific tendencies, but æsthetic ones also, as, indeed, a lover of flowers must have; and we were but the mouthpiece of many who, some years since, admired and upheld his bold departure in the way of exhibiting Roses at the Royal Botanic. It was a triumphant vindication of our oft-expressed regret that it should be the practice to exhibit some of the most beautiful flowers in the whole range of gardening in the most uncompromisingly conventional manner that it is possible to adopt.

The descriptive articles on trees and shrubs, and on their use in landscape gardening, will be very serviceable for reference, but they do not call for comment in this place.

Under the title of *An Hour with the Hollyhook*, we have a reprint of a pamphlet originally published in 1855, and full of information on the subject on which it treats. A reference to the peculiar structure of the stamens in this plant under normal circumstances would have illustrated the way in which they become double, and might serve as a guide to the thoughtful cross-breeder. Alluding to the Hollyhook disease, which more than decimated the plants a few years ago, but which has now disappeared, Mr. PAUL attributes its prevalence to "the unwholesome plan of forcing the plant, causing it to grow out of season, and in a close unnatural atmosphere, in order to obtain a more rapid and extensive increase by root-grafting." No doubt the conditions mentioned by Mr. PAUL are likely to weaken a plant's power of resistance to adverse circumstances, but the actual cause of the mischief is well-known to be a fungus, *Puccinia malvacearum*, which was as common on the wild Mallows of our hedgerows and field-sides as it was in the Hollyhooks in our gardens. The wild plants, at least, had not been subjected to the debilitating influences to which gardeners sometimes subject their victims. Every year we see some of our wild Mallows affected with the pest, but we are quite ignorant of the conditions which caused it suddenly to assume the characters of an epidemic, and as suddenly to relapse into its comparatively quiescent state. Forcing or no forcing, there can be little doubt that we or our successors will sooner or later be called on to witness another outbreak, and then, as now, we shall probably find the hardy "peasant-plant" resist the attack better than the pampered dandy of the forcing-pit.

Hyacinths form one of Mr. PAUL'S many specialties. We cannot give space to the subject further than to make a passing comment on his statement, that "it would be commercially unwise to enter the field against such skilful and indefatigable contemporaries [as the Dutch]. We can buy and sell cheaper than we can produce." This is, no doubt, true as a general statement; but the experience at Kew for the last two or three years tends in the opposite direction, and we have ourselves heard—we might almost say, known—of the successful culture of bulbs in the sandhills near Sandwich. The bulbs were grown, and put upon the London market, but though the quality was not objected to, no purchaser could be found for them, because the grower would not guarantee them to be "Dutch bulbs." Those very bulbs, if our memory be not treacherous, were subsequently bought by the late Mr. VAN HOUTTE, and transferred to Belgium! Whether this be true or not, all visitors to Mr. VAN HOUTTE'S nursery in spring will recognise that Dutch surroundings are not exclusively necessary for the successful culture of Dutch bulbs, and there is no doubt that we could, "an' we would," grow our own Hyacinths; and a time may come when it will be as commercially advantageous to do so as it is already in the case of Narcissus.

The lecture on the Camellia and its culture, delivered before the Royal Horticultural Society, is an admirable summary of the principal points in the culture of this valuable shrub, while the following articles from our own columns in 1879, contain an exhaustive account of the plant from a horticultural point of view, and a descriptive list of the best varieties.

RHODODENDRON NUTTALLI, IN LORD ANNESLEY'S CONSERVATORY.

The third section of the book, containing the author's remarks on Fruit Culture, need not detain us at any length, as the subject is so recent and is still occupying so much attention. Mr. PAUL believes that there are "thousands upon thousands of acres of land in Great Britain and Ireland, which are at present yielding little or no profit to owner or cultivator, which might be made to yield a handsome return to both if planted with fruit trees; but it is the capitalist who can afford to employ skilled labour, and wait for the returns that must set the machinery in motion."

The lecture delivered at the provincial show of the Royal Horticultural Society at Manchester on the "Improvement of Plants," is, if it be not the most valuable, one of the most important, chapters in the whole book. It details the methods which have enabled horticulturists to make such wonderful advances during the last half-century, and it offers to the thoughtful agriculturist countless examples, which he would do well to imitate according to circumstances.

Two pleasantly-written chapters close the book, one on the literature of gardening, and another on the dawn of landscape-gardening in England. But our notice has extended to such a length, that we shall run the risk of defeating our own object, which is to induce the gardening reader to peruse this "mixed border" of a book for himself, in the full assurance that he will find very much to instruct, and even more to interest him.

RHODODENDRON NUTTALLI.—We are indebted to the kindness of the Earl of ANNESLEY for the opportunity of figuring a fine plant of *Rhododendron Nuttalli* growing in his winter garden at Castlewellan, co. Down, Ireland. The species, a native of Bhotan, is deservedly a favourite with his lordship, from the large size of the flower and the lovely pale green and creamy tints of the interior of the flower-tube.

NATIONAL CHRYSANTHEMUM SOCIETY.—For the first time, the Society will hold an exhibition on October 12, 13, and 14, and, as usual, at the Royal Aquarium, Westminster, so as to afford an opportunity for the exhibition of the October-flowering Japanese varieties introduced during the last few years. A Conference will take place on the evening of the 12th, at 7 o'clock, in the library, to discuss the suggested alteration in the size of show-boards used for blooms of Japanese varieties, and to hear papers read by Messrs. C. E. SHEA, W. H. FOWLER, R. FALCONER JAMESON, and E. C. JUKES. The President of the Society, Sir EDWIN SAUNDERS, will take the chair.

CHRYSANTHEMUMS IN THE LONDON PARKS.—Mr. J. J. COPPIN, the Superintendent at Battersea Park, informs us that the exhibition of Chrysanthemums in that park will be open to the public on Saturday, October 15, in the Frame Ground, near the Albert Bridge entrance.

—The twelfth annual display of Chrysanthemums in Finsbury Park will be open to the public daily at ten o'clock, and will be at its best some two or three weeks hence.

STATISTICS OF THE NATIONAL ROSE SOCIETY'S EXHIBITS.—Mr. GRAHAME furnishes us with a reply to "Wild Rose's" last communication, and in which he states that his (Mr. GRAHAME'S), figures are the official figures of exhibits staged as recorded at the time, whilst he continues to challenge the accuracy of "Wild Rose's" enumeration. We do not think this is a matter which can be any further discussed advantageously in our columns. Mr. GRAHAME himself is willing to refer the whole question to "a thoroughly competent and unbiassed authority," and when that has been done we shall be pleased to publish the conclusions arrived at. We are in this

particular matter only concerned with principles, and have not space for the discussion of details.

ONE MORE GARDENING PAPER.—Under the title of *Cottage Gardening*, Messrs. CASSELL & Co. are about to publish a new halfpenny weekly journal, dealing with gardening and kindred subjects. It is specially intended to help the occupiers of small gardens, poultry and bee-keepers, allotment-holders, and housewives. It will be edited by Mr. W. ROBINSON, F.L.S., founder and directing editor of *The Garden*, and will be fully illustrated. The first number will be published on the 12th inst.

COMPLIMENTARY DINNER TO MR. H. E. MILNER.—This took place in the French Restaurant of the International Horticultural Exhibition on the 29th ult., and was attended by nearly 100 gentlemen, including Sir Charles Tupper, Sir J. Heron Maxwell, Bart., Baron de Reuter and Baron G. de Reuter, Professor Stewart, President of the Linnean Society; Colonel Cody, Nate Salisbury, Major Burke, G. A. Loveday, Messrs. A. Waterer, W. Paul, John Lee, W. Bull, P. Barr, J. Laing, H. Turner, A. Turner, F. J. Lane, O. Thomas, A. F. Barron, H. Herbst, &c., as representing the horticultural body. Mr. H. Percy Dodson, the chairman of the dinner, and one of the directors of the exhibition, presided. In proposing the health of Mr. Milner, the chairman alluded to the immense amount of work which devolved upon him, and during the whole time the exhibition had been open matters had progressed in the smoothest manner, thanks to the good management of the chairman of the executive committee, their guest. The chairman then presented Mr. Milner on the part of the leading officials of the exhibition and others with a massive silver salver as a memento of the exhibition. On rising to respond to the toast of his health, Mr. Milner was accorded a most gratifying reception, and said that all the officials of the exhibition had but one object in view—the success of the gigantic undertaking. This was due in a great measure to the directors and the members of the staff, who had all worked most energetically. Their flower shows had surpassed their expectations; they had been the means of attracting large numbers of persons to the exhibition. They had aimed by means of these exhibitions, by lectures, &c., to disseminate a love for gardening among the people, and he believed their efforts had been much appreciated. Mr. Milner made particular allusion to Mr. W. Marshall, Mr. H. Turner, Mr. R. Dean, and other horticulturists, and also to the liberal support he had received from the horticultural trade. The number of visitors up to the present time was nearly two millions, and he was happy to say there had been no accidents, or occurrences to deplore. Some other speeches, and some excellent music, enabled a very enjoyable evening to be spent.

HARVEST FESTIVALS.—We print the subjoined circular, in the hope that other of our clerical friends will go and do likewise:—"The Vicar of Shirley, near Croydon [Secretary, Royal Horticultural Society], being an enthusiastic gardener himself, and knowing better than most people the difficulties of a gardener's life, and their generally straightened means, hopes the congregation at Shirley will enable him to send up a goodly contribution to the Gardeners' Royal Benevolent Institution, to which the offertories at the harvest festival will be devoted. An account of the Society is given in the Shirley Parish Magazine for October." To this we can now add that the church at Shirley on October 2, was tastefully and appropriately decorated with Asters, and that as a result of Mr. WILK'S appeal, a sum of over £30 has been added to the funds of the Gardeners' Royal Benevolent Institution.

PROPOSED CONGRESS OF BOTANISTS OF THE WORLD AT CHICAGO.—The following letter appeared in the *Times* of October 1:—"The above is one of the things which are under consideration by the people of the United States at the World's Fair next year, and which Dr. ARNOLD brought under the

notice of botanists and others at the recent meeting of the British Association. I do not know if much advance in knowledge in certain fields of botany would be made by such a congress; but I believe that such a meeting of those botanists who are connected with economic botany would do a large amount of good. For example, I shall touch upon a few points in regard to the position of agricultural botany in our own country, where the difference of opinion on some points between the botanical representatives of some societies is remarkable, while the difference of opinion on some points between those 'authorities' who talk and write about agriculture and those who are engaged in the industry is very wide. First comes the remarkable and somewhat curious publication in the *Journal* of the Royal [Agricultural] Society, where the results of some experiments which were altogether exceptional led the botanical representative to condemn the use of the farmers' most extensively-used grass. Next, we have what was called a great controversy on the point, when another consulting botanist and professor of agriculture got turfs from various rich pastures, and studied the growth of them, which, doubtless, somewhat redeemed the character of Ryegrass, although every observant farmer knows that if he removes turfs from one part of his farm to another there is a wonderful transformation of the herbage; and what formed a great controversy to so-called theoretical men was of little value to practical men. Turning next to the doings in Scotland, we find the botanist of the Highland Society producing a work, by which he shows that grasses can be identified by their leaves, with a curious point, that a professor of agriculture writes a preface recommending that of which he practically knows nothing, he being no botanist who could claim precedence of the author for whom he writes the preface; while a principal of an English agricultural college devoted a long article in exaltation of this work in a leading agricultural publication, where he has charge of the crop department. We find the botanist of the Royal [Agricultural] in his capacity of botanist to the Bath [and West of England] Society in a recent article recommending that to identify the grasses a part should be enclosed so as to allow the plants to flower, when the foliage could be compared with that of the pastured part, and thus the plants of the latter could be identified. A representative congress before publication would have either given this book standing or prevented publication, with the view of recognition as a reliable work. Then we have the preface to the English translation of the Swiss authority's work, bearing out that what suited the Swiss was bound to do with the Britisher. The Americans are ready to take up new ideas, and the country being young much less attention is devoted to rotation than in Britain. But a great change may require to take place in their system of husbandry in the future, which latter makes them alive to novelties. Behind these matters, just touched upon, we have the acknowledged advances of crop cultivation by farmers themselves. This is true science, and much might be gained by a thoroughly representative congress. While we have seed farmers who study the strains of farm plants, and from time to time add something of value along with horticulture, forestry, and so on, with a wide field for improvement, such work is capable of much wider development, and should the people of the great Republic of the West be enabled to organize a congress of this department of botany, it seems evident to me that much might be done to modify these differences of opinion, eradicate the publication of immature or insufficiently-discussed matter, produce more harmony among the three classes referred to—viz., farmers, seed farmers, &c., and professors—give an impetus to further progress, and greatly increase the produce of the land.—WILLIAM WILSON, Alford, Aberdeen N.B." [We believe that the botanists have decided not to hold a congress at Chicago; but the subjects above-mentioned belong rather to agriculture, and a gathering of the officers of the numerous agricultural Stations in America is very likely to be held, and

would form an appropriate tribunal before which to discuss the matters referred to in the above communication. ED.]

ROSA RUGOSA.—Mr. SMITH, Daisy Hills, Newry, who seems always to have something new and interesting, sends us a box of specimens of *Rosa rugosa*, some of the ordinary type with large bold foliage and fruits of the size of a small Plum, whilst others are scarcely bigger than a black Currant, the foliage being correspondingly diminished. The form, moreover, varies. The typical form has the fruits of the shape of the earth! spherical, but flattened at the poles, but the variety *pyriformis* has small leaves, white flowers and Pear-shaped fruits. The prickles appear the same in all the varieties and—very sharp.

CACTUS DAHLIAS.—We have received a number of seedling Cactus Dahlia blooms from Messrs. H. CANNELL & SONS, Swanley. They are of bright colours, and exhibit good form, although we think that for general usefulness and effect, none of the newer varieties beat our old favourite *Juarezii*. One of the blooms from Mr. CANNELL is described as a "Pompon" Cactus. It is somewhat smaller than the rest, but we can hardly consider it a Pompon.

GRASSES OF NEW SOUTH WALES.—In the *Agricultural Gazette of New South Wales*, published by the Department of Agriculture, Mr. F. TURNER continues his illustrations and descriptions of the grasses of Australia. The illustrations are particularly serviceable.

"AGRICULTURAL GAZETTE OF NEW SOUTH WALES."—This useful publication, which is issued by the Department of Agriculture at Sydney, contains articles on the grasses and forage plants of the colony, notes on the diseases of plants, and on insect enemies, together with much and varied information on points of practical agriculture.

AUSTRALIAN FUNGI.—From the *Kew Bulletin* we learn that Dr. M. C. COOKE has prepared a handbook of Australian fungi, including 2084 species. The genera are illustrated by thirty-six plates, twenty of which are coloured.

IRIDS.—We are glad to learn from the *Kew Bulletin* that Mr. BAKER has in the press a handbook of Iridaceæ, uniform with those which he has already published on Amaryllidæ and Bromeliadæ. The order contains about sixty genera, and 800 species, nearly half the latter being concentrated at the Cape. The large garden genera are *Crocus*, *Iris*, and *Gladiolus*.

"ANNALS OF HORTICULTURE, 1891."—Under this title the Rural Publishing Company, of New York, have published what is termed on the title-page, "a witness of passing events, and a record of progress." Its compilation has been entrusted to the very competent hands of Prof. L. H. BAILEY. It deals with fruits and fruit-culture, decorative plants, plant diseases, and other matters which are common to all countries, whilst the latter portion is concerned with lists and directories specially useful to the citizen of the States. One special feature is the census of wild American plants now introduced into commercial cultivation. Assuming that there are about 10,000 species native to America, north of Mexico, Prof. BAILEY estimates that 2416 are, or have been, in cultivation. This is satisfactory, as one of the silliest traits of fashion is to overlook native plants, and yearn after those less attainable, and less suited to the climate. Another valuable item is the list of papers and reports on horticultural and cognate subjects published by the various agricultural experimental stations. We cannot cite all the varied contents, but we may say that the book is one which no one who wants to keep *au courant* with the progress of horticulture can afford to dispense with.

BOTANICAL NOMENCLATURE.—From the *Botanical Gazette*, for September, we extract the following rules for nomenclature, which have been adopted

by the Botanical Club of the American Association for the advancement of Science.

"Resolved: That the Paris Code of 1867 be adopted, except where it conflicts with the following recommendations:—

I. *The Law of Priority.*—Priority of publication is to be regarded as the fundamental principle of botanical nomenclature.

II. *Beginning of Botanical Nomenclature.*—The botanical nomenclature of both genera and species is to begin with the publication of the first edition of Linnæus' *Species Plantarum*, in 1753.

III. *Stability of Specific Names.*—In the transfer of a species to a genus other than the one under which it was first published, the original specific name is to be retained, unless it is identical with the generic name, or with a specific name previously used in that genus.

IV. *Homonyms.*—The publication of a generic name or a binomial invalidates the use of the same name for any subsequently-published genus or species respectively.

V. *Publication of Genera.*—Publication of a genus consists only (1) in the distribution of a printed description of the genus named; (2) in the publication of the name of the genus and the citation of one or more previously-published species as examples or types of the genus, with or without a diagnosis.

VI. *Publication of Species.*—Publication of a species consists only (1) in the distribution of a printed description of the species named; (2) in the publishing of a binomial, with reference to a previously-published species as a type.

VII. *Similar Generic Names.*—Similar generic names are not to be rejected on account of slight differences, except in the spelling of the same word; for example, *Apios* and *Apium* are to be retained, but of *Epidendrum* and *Epidendron*, *Asterocarpus* and *Astrocarpus*, the later is to be rejected.

VIII. *Citation of Authorities.*—In the case of a species which has been transferred from one genus to another, the original author must always be cited in parenthesis, followed by the author of the new binomial."

"DICTIONNAIRE PRATIQUE D'HORTICULTURE."—The French translation of NICHOLSON'S most useful *Dictionary of Gardening* is advancing under the editorship of M. MOTTET. Additions and corrections have been made, so that those in possession of the English edition will not find it superfluous to possess the French one also; at least, all libraries of reference should place it on their shelves. The publisher is OCTAVE DION, 8, Place de l'Odéon, Paris; or it may be obtained here through any foreign bookseller. Coloured plates form a feature, which was not possessed by the original edition.

COLUMBIAN EXPOSITION.—Mr. E. C. CULP, Secretary to the Joint Committee on Ceremonies, informs us that the Congress of the United States, at its recent session, having changed the date for the dedication of the buildings of the World's Columbian Exposition, Chicago, from the 12th to the 21st of October, 1892, he is directed to give notice of such change of date to all who have received invitations to these ceremonies.

"THE AGRICULTURAL RECORD."—This is the official journal of the Central Agricultural Board of Trinidad. It has entered upon a new series, under the management of our energetic correspondent, Mr. J. H. HART. On the subject of education, the Editor notes that there is a sort of rivalry between the Professors of Chemistry and of Botany in respect to agricultural teaching; while the practical man would have the student go through the old-fashioned forms of apprenticeship, and limit or exclude class and laboratory teaching altogether. But it is pointed out that in France this plan was tried, and fell into disrepute. No doubt the right course is, as the Editor says, so to "arrange our plans as to obtain the services of all."

A SCHEME, says the *Builder*, for the purchase of the open space now used at Earl's Court for exhibition as a public park, appears to be in the air. There is no

doubt that it would be a great public advantage if this land could be utilised for this purpose. From a purely financial point of view it would well repay the owners of houses in this district to combine to purchase this land, as it would greatly improve the district as a residential neighbourhood. Although South Kensington and Brompton are crowded with what builders have jocularly called "gardens," these are, in most instances, comparatively narrow streets, and one great drawback to this part of London is the absence of any large open public park or gardens. We have some doubt, however, whether sufficient energy and organisation will be given to this scheme, and we should not be surprised to see this space remain an exhibition ground for some time to come. But nothing would do more for the health of this district, or tend more to raise its somewhat declining favour as a place of residence, than a park at Earl's Court.

THE DEVON AND EXETER GARDENERS MUTUAL IMPROVEMENT ASSOCIATION.

—The autumn programme of session 1892-93 is as follows:—Wednesday, October 5, Mr. J. McCormick, Wear House Gardens; subject: "Grape Vines and their Cultivation." Wednesday, October 19, Lieutenant Percy Smith, Devonshire Regiment, Higher Barracks; subject: "Lilies and their Culture." Wednesday, November 2, Mr. J. Stoneman, Teacher of Botany at Exeter Museum; subject: "How a Scientific Knowledge of Plant Life can help a Gardener." Wednesday, November 16, Mr. G. B. Carlisle, Topsham; subject: "Fruit: its selection and handling—from a Fruit-salesman's standpoint." Wednesday, November 30, Mr. J. Mayne, Bicton Gardens; subject: "The Cyclamen: its Culture and Value as a Decorative Plant." Wednesday, December 14, Discussion on papers read last session. The secretaries are Messrs. Andrew Hope and T. E. Bartlett.

CATTLEYA REX.—Messrs. LINDEN'S sale at Messrs. PROTHEROE & MORRIS' Rooms on Friday, September 30, was a success, and the quantity of plants of this new *Cattleya*, which formed the principal attraction, went well, the best pieces realising from five to fifteen guineas each.

UNITED HORTICULTURAL PROVIDENT AND BENEFIT SOCIETY.

—The sixth annual dinner of the society was held on Wednesday, the 5th inst., in the Cannon Street Hotel. Upwards of 150 guests were present under the genial chairmanship of JNO. FRASER, Esq., of Lea Bridge. The chairman, in proposing the toast of the evening, referred to the advantages which the society offered, and to the satisfactory condition into which it has now been brought from the not too prosperous state in which it was for some years. In Mr. FRASER'S words, the society had been removed from the condition of cold adversity into the sunshine of prosperity. This result has, no doubt, been brought about by the indefatigable efforts of the officers, and by the merits of the Society itself. There are now something like £7000 in the funds of the Society, and the membership continues to show a steady increase. The convalescent fund, which was started by Mr. SNEUWOOD, has been making headway, and last evening Mr. SHERWOOD managed to collect something like £30 to be placed to the credit of that fund. This Society is in no way a rival to the other horticultural benevolent associations, and as Mr. W. MARSHALL said last evening, in this Society the members help themselves, the Gardeners' Benevolent Society is to help those who have no longer the means to help themselves, and the Gardeners' Orphan Fund was to help those who were from other causes unable to help themselves. The gathering was made the opportunity to present to Mr. JAMES HUDSON, the Treasurer of the Society, a very elegant gold watch and chain, together with a testimonial, showing the members' appreciation of the unique services rendered by Mr. HUDSON during the last ten years, and expressing the hope that he might long live to continue his useful career, and to enjoy the happiness that the subscribers hoped might be his.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.—We are requested to state that the fifty-third anniversary festival Dinner of this institution will be held on November 15 next, at the Hôtel Métropole, when the Chair will be occupied by Lord BRASSEY, K.C.B. Gentlemen desirous of being present should make early application for tickets to the Secretary, at 50, Parliament Street, London, S.W. The Secretary also desires us to say that he will be obliged if friends, who have not already done so, will kindly send in their collecting cards before that date.

HOME CORRESPONDENCE.

STEAM VERSUS HOT WATER.—In reading over the *Gardeners' Chronicle* of September 24, I was much struck with the article under the above heading by Mr. Thomson of Clovenfords. Having read the editorial article he refers to, which appeared in your previous issue, setting forth Mr. Caird's theories upon steam-heating, I came to the conclusion that Mr. Caird had not in any way over-estimated its value. Having arrived at this conclusion, I was all the more surprised upon reading Mr. Thomson's article. Mr. Thomson seems to have a great dislike to steam being used for horticultural purposes, so his letter would lead one to believe, and yet he only gives one instance of where he had steam as a heating medium. I fail to see his grounds for such antipathy. He mentions as an instance, Wrotham Park, near Barnet, in the year 1837, when he had charge of that place, and the steam-heating there was a failure. Had he found the place heated by hot water instead of steam, with the same amount of pipe-surface, it is quite natural to suppose the results would have been the same. It was not the boiler that was at fault, but the small surface of piping. That was no true test. Had he given the extra pipe-surface to his steam-boiler, it is just possible he would have had as good results as he derived from hot water with steam-boilers. There is no necessity for the attention of a "skilled engineer and his mate." How many skilled engineers are employed as firemen at public works? and they run steam-boilers. Then the cost of steam-pipes is double that of hot-water pipes. Mr. Thomson says such was probably the case in 1837, when steam was in its infancy, but it is just the other way to-day; 2-inch pipes of malleable iron, having a screw-joint, is all that is necessary; no indiarubber-rings are required—at least, so far as I have seen. Steam is much the better medium for large places, or where there is a great length of pipe. I will give you an instance where hot water failed to do that which steam accomplished. In this case it was not possible to have the boiler-house near the plant-houses without creating an eyesore, and so it was put 100 yards away from them. Hot water was tried, but failed, owing to the length of pipe it had to travel before it reached the houses, and steam was resorted to, and turned out a complete success. Two boilers were put in, and worked at low-pressure; the main-pipe was brought up the centre of a walk at 3 feet from the surface, and led into an overhead tank, in a passage at the end of the houses. The pipes supplying the houses all came from this overhead-boiler, which was fed, as I said, from the main-pipe leading from the boiler-house. This overhead-tank, where the steam was stored, was intended to help the fireman by allowing him the necessary time to get up his fires, should the temperature fall suddenly, an occurrence very common in the Eastern States of America during the winter. At this place, belonging to the Hon. F. Jones, Portsmouth, New Hampshire, there are some twenty-two houses all heated by steam from the before-mentioned overhead-tank or boiler, consisting of Peach-houses and vineries, propagating and Rose-houses, one Carnation-house, and one tropical-house (stove); all the piping was under the stages, which were built of iron and slate, only the Rose-houses having one overhead pipe, which was covered with felting and white canvas, and provided with a drip-pipe, connecting the overhead-pipe with the return-pipe under the stage. All the pipes were of 2 inch diameter. I had charge of the tropical-house and Orchids, a range 120 feet long by 24 wide, and running north and south, with a door at each end. The flow-pipes came into the house, one on each side of the door, into a manifold pipe, into which all the other pipes that passed down each side of the house, six in number (on each side) were screwed. On this manifold pipe were six valves,

one for each pipe let into it, and then at the other end these six pipes ran into another manifold having a valve for each pipe let into it. This manifold was connected with the return-pipe, and where the flow came in at the side of the door, there was a valve for itself. When steam was wanted, I opened the valve on the main or flow-pipe, which let the steam into the manifold, then I opened the valves of as many pipes as I thought were necessary on the manifold at the flow end. Then, passing along to the other end of the house, I opened the corresponding valves on the manifold, and also the blow-off valve, allowing it to stand open until all the air and water were forced out, and when the steam came I closed it. From what I have said, it will be seen that the temperature could be modified much easier than with hot-water, as I could have one or two, or all the pipes in use, just as I desired, as each pipe was independent of its neighbour. The last winter I was there we had a cold spell, during which the thermometer registered several times 6° below zero, and, with all the twelve pipes going, my house never was below 60°, and had there been any evil effects of steam whilst I was attending to the houses, it would have made itself felt. The boilers were two in number. One was used at a time, and changed every fortnight. They were attended by a labourer only, and, during the cold spell, the fires required attention every four hours, both boilers being at work at that time. The consumption of coal for the season was about 200 tons. I will give you some of the reasons why steam is better than hot water. During the winter in America the sun is a powerful agent in raising the temperature in greenhouses, so much so, no matter how cold the night, in the morning, when the sun bursts out, all artificial heat can be dispensed with. With steam five minutes after you turn off the pressure, the pipes are cold, so that you can keep your houses at an even temperature without putting on air. Such would not be the case with hot water, as then the pipes would remain hot for a long time after shutting the valve; then again, on turning on heat, the pipes are hot inside in one minute with steam, not so with hot water. These facts are in favour of steam, I think. I worked in another place, where hot water was the medium. There we had three boilers and 4-inch cast-iron pipes, and during the season 120 tons of coal were burned, and there were only thirteen houses, and this was in New York State, which does not have the cold spells common in New Hampshire; but when we had zero-weather, the fires had to be looked to every two hours during the night, and at the end of each house there was a large expansion-box, as the pipes would never have stood the pressure without them—that was hot water. In conclusion, I may say hot water cannot be compared with steam as a heating agent: both have been given a fair trial all over the States, and the hot-water heating is constantly giving way in favour of steam, as being the cheaper and more efficient. A proof of this may be found in the fact that the largest places, and which are owned and worked by practical and scientific men, are now heated by steam. *John Stewart, Cartnall, Paisley.*

ROSES IN BRITISH GUIANA.—In reply to Mr. F. im Thurn, p. 408, I find the hybrid China Rose, "Reine Marie Henriette," one of the best red varieties for forcing. Cheshunt Hybrid is also a valuable kind; both make very strong growths indoors, similar to Maréchal Niel, and should be treated accordingly. The best plan being to prune them hard back as soon as flowering is over, and then to encourage a vigorous growth for flowering the next season. I remember how well Maréchal Niel was growing and flowering in the hot sandy soil of Florida, but I did not see any red variety there in quantity. Messrs. Peter Henderson & Co., New York, spoke very highly of H. P. Magna Charta, as one of the very best Roses for forcing; but it can only be classed as rose for colour. We have a dark red Tea Rose, Souvenir de Thérèse Levet, which does well in pots under glass; but with us it is only a moderate grower, and possibly might not prove vigorous enough for a very hot climate. As regards transportation of Roses, I had a plant of R. Sinica sent from Florida in March, which was merely wrapped tightly in oiled paper, with a little dry sphagnum-moss round its roots, and then sent by letter-post a journey of 12 to 14 days; the top had been cut down near to the root, and about an inch was projecting beyond the oiled paper; it had commenced to grow during transit. The plant was quite a young one, probably about 12 months old. It is now growing well, and has made a good plant. For sending out

from England, I should time Roses to arrive, if possible, at the commencement of the rainy season. *W. H. Divers, Ketton Hall Gardens, Stamford.*

ROSES FOR THE TROPICS.—In the *Gardeners' Chronicle* of October 1, Mr. Everard F. im Thurn asks for information concerning Roses in British Guiana. I have planted Roses in the Botanic Garden of Buitenzorg, Java, for more than twenty years. I suppose our climate in Java is not very different from that of Guiana. We have in our garden two large Rose-beds, each containing 1500 plants. In Europe, the dominating colour is red; in Java, white, yellow, and rose are the colours of the majority of flowers. The cause is, that nearly all the Tea Roses do very well, also most Bourbons, Noisettes, and the small-flowering Polyaontha Roses, but the group which contains the darkest Roses; the hybrid-perpetuals, gives us much trouble. It is not easy to make out why some varieties of this group flowers freely, and others grow well, but never flower. I planted them in different manners, without much success. All Roses which in Europe are not truly perpetual, will never bloom well in a hot climate; therefore, we must only plant those varieties which are in Europe the most perpetual. Among the group of hybrid perpetual Roses, Victor Hugo, American Beauty, Lord Raglan, Géant des Batailles, Earl of Pembroke, and Madame Moreau, are flowering very well; the last-named is one of our best dark red Roses, but the plant must not be pruned too short. It produces only its splendid large flowers on long branches, as is the case with Paul Neyron, which with us also produces flowers as large as I ever saw them in Europe. Captain Christy and Merveille de Lyon give from time to time good flowers, but not so many as the first-mentioned. In a tropical climate the plants grow all the year round; therefore, we give them plenty of manure. The flowers of our Roses are, perhaps, not so large as in Europe, but we have always flowers. Every day of the year I have fresh Rose-flowers in my house. The Roses of the group *Rosa indica fragrans hybrida*, the so-called hybrid Teas, are also very good for warm countries. Beauty of Stapleford, Countess of Pembroke, La France, Madame Alex. Barnain, Michael Sanders, Lady Mary Fitzwilliam, are all first-rate Roses for the tropics. The Botanical Garden of Java publishes three periodicals, the first is the *Annales du Jardin Botanique de Buitenzorg*, the second the *Mededeelingen uit's Lands Plantentuin*, the third is *Tegsmania*. The last is the most popular; therein are written many articles about Rose-culture in the tropics. *Wigman, Curator, Bot. Garden, Buitenzorg, Java.* [We are much indebted to our correspondent. His experience as curator of one of the finest gardens in the tropics, if not the very finest, is very valuable. Ed.]

—I have never been in the tropics, but have had considerable correspondence about Roses and Rose culture in tropical countries. One thing is very clear to me, namely, that the varieties of R. indica, Chinese, Tea-scented, and Bourbons, are the easiest to deal with there. The Noisette, Bourbon, Perpetual, and Rose de Rosomène stand next in order. Your correspondent, if fond of Roses, should grow every Tea-scented Rose he can lay hold of. The best of the hybrid perpetuals for his climate I should judge to be, Albert de Blotais, Augustine Guinoisseau, Captain Christy, Daomark, Duchess of Albany, Gloire Lyonnaise, Madame F. de Forest, Madame B. Darschmidt, Marchioness of Lorne, Gloire de Margottin, Marie Paré, Madame F. Pittet, Madame I. Pereire, and Madame A. Perrin. These have a good deal of the Chinese blood in them. But for dark red Roses, he had better trust to the Chinese or Bengal Roses. Copious watering, free shading, and strong soil would seem advisable. The best time for the plants to leave England is between October and December. *William Paul, Waltham Cross, Herts.* [To the above we may add from *Hints on Gardening in India*, by G. Marshall Woodrow, that all Roses must not be treated alike as regards pruning. "In the Noisette class, which includes the yellow Roses, Lamarque and Solfaterre, that are so common in India, the weaker shoots should be cut out, and the stronger ones reduced to about a third of their length. The proper season for this operation is when the tree is at rest during April. . . . The long rampant shoots may be pinched at the points, as the Noisettes bloom from the side shoots. Hybrid perpetuals, which include most of the rich dark colours, are benefited by hard pruning during the season of rest in April. At this season all the shoots of the past season should be cut to within four buds

from their origin. As these Roses flower at the ends of strong shoots, these should be left intact till they have flowered, then a few of them should be cut back as before; this prolongs the flowering, but if too many are cut back, it weakens the tree. Tea Roses require varied treatment; strong growers, such as M. Niel and Gloire de Dijon, should be treated as above detailed for Noisette Roses; weak growers should have all the shoots that have flowered cut back to within four buds of the base, and all weakly and barren shoots cut back from time to time during the growing season. China Roses should be cut back several times during the growing season. Bourbon Roses require little pruning beyond taking off the ends of shoots that have flowered, and cutting out such as are weakly." It is very necessary to plant Roses on raised, well-drained sites, to prevent injury to the plants, owing to flooding of the roots during the rainy season. En.]

A LARGE PAULOWNIA IMPERIALIS.—We have here growing on the lawn a fine tree, 45 feet high, and 30 feet in the spread of its branches, girth 7 feet 6 inches, being 3 feet from the ground. It flowers freely most years. The frosts of the last two winters have not injured it in the least. *G. Hunt, Ashted Park, Surrey.*

THE APPELEY TOWERS GRAPES.—Being at Ryde last week, I took the opportunity of making a call on Mr. Miles, the gardener at Appley Towers, to see the new Grapes, which he raised from seed, viz, Appley Towers, a black Grape, very distinct, with large-berried compact symmetrical bunches, which colour well, and have excellent keeping qualities, having been kept as late as the month of May in good condition. The other, a white Grape, is Lady Hunt. Two Vines of this variety were heavily cropped with capital large bunches, having broader shoulders than the other. Both are distinct, and so good that they are worthy of general cultivation. *J. C. Mundell, Moor Park Gardens, Rickmansworth.*

CARNATION WINTER CHEER.—Cultivators of Carnations for winter-flowering, who do not already possess this variety, should not fail to get it, as not having, perhaps, its equal for winter blooming. It is good in every way, and there is no difficulty with its propagation, cuttings rooting readily; it also grows freely, and its scarlet blossoms, which are of good substance and form, are produced abundantly. I saw recently at Goodrich Court, Ross, a frame filled with a fine lot of it, splendidly grown in 6-inch pots. These plants were forming so many flower-buds that Mr. Spencer had good reason to be proud of them, as he seemed to be. *Thos. Coomber.*

SOME BULBS TO PLANT AT THE PRESENT SEASON.—We all of us plant Tulips, Narcissus, Crocus, single Hyacinths for spring flowering, and in this we do well, but the bulb beds, if they are not carpeted with Pansies, Violas, Winter Aconite, Ajuga, Bellis, Arabis, &c., might be planted with the various Scillas, which do not grow so tall as the other bulbs. The best are *S. amona* and *S. bifolia*, the former, which is very low growing, associating well with the dwarfier of these; and the latter with Hyacinths and Narcissus. *M.*

DYMOND PEACH, ETC.—If I were limited to one Peach only, I should grow Dymond. It is a good doer, showy, and of first-class flavour. For a good late Peach, I prefer Gladstone to any other variety. Picked before it is ripe, this Peach keeps well for two weeks. For a Nectarine either early or late, none can beat Pine-apple, it is showy, of excellent flavour, keeps well after gathering. For a Nectarine it grows well. *Morgan.*

GYPSOPHILA PANICULATA.—In reading the remarks (p. 395) anent Mr. Dod's garden, I was surprised to learn that the cultivation of this plant embodied any secret; for in our garden it grows as freely as any other hardy border plant. The soil is stiff, cold, and retentive, and contains much chalk. One small root, which threw up from weakly-looking growths, developed into a magnificent bush 5 feet across and 4 feet high. This is a plant which should be more commonly cultivated, if only for its value for mixing with cut flowers. *E. M.*

STRIPED SWEET BRIAR.—This Rose, which was awarded a First-class Certificate by the Royal Horticultural Society, and has been sent out by Messrs. Paul & Sons under the name of Janet's Pride, has this year added to its value by giving a fair quantity of autumn blooms, of which I send you a specimen. *Wild Rose.*

VARIEGATED VINE.—As it is an unusual thing to hear of Grape-vines sporting, I forward, this post, for your inspection, three leaves from a sport (a lateral), which is its second year. The variety from which the sport is on is Black Alicante. Last year it bore a small bunch of Grapes, which I thought were going to remain white; but they finally turned black, though in doing so they were a most beautiful colour (puce); in my opinion, it will make a most beautiful and interesting climber for warm conservatory. No variegated leaf, to my knowledge, is so delicate in its markings. I shall try to fix it. *May-flower.* [Leaves almost pure white; incapable of growing by themselves. En.]

VICTORIA REGIA.—In your issue of last Saturday, there appears a statement, signed "J. P., Cherkley Court," to the effect that the first bloom of my Victoria regia this year opened on May 1. Will you kindly insert in your next number a contradiction of this erroneous statement, as the first bloom opened at the end of February, not at the beginning of May. The plant has continued in bloom ever since, usually with a bud as well as the flower; and I hope it will bloom periodically, although not continuously, till the middle or end of December. *Abr. Dixon.*

CERTIFICATES AT THE ROYAL HORTICULTURAL SOCIETY.—Your correspondent, at p. 409, would have made his case stronger had he confined his notes to the granting of Certificates in general, instead of selecting me because I exhibited one of Messrs. Veitch's new Peas. Of course, he fails to see what bearing my note had on giving Certificates to other things grown at Chiswick; he ignores the two first questions I raised, which were precisely similar; only those points affecting my own case are brought forward—he does not care for other Certificates. With regard to Mr. Myles' new Grapes and Mr. Allan's Strawberries getting Certificates freely, let me inform him they were voted chiefly by that portion of the committee which represent the gardeners; indeed, in both instances, I can claim to have proposed some of these Certificates. As to his surprise at some of the exhibits sent, much depends; this surprise is not shared by the larger portion of the committee. Admiration in such cases is not expected from any critic, but fair play. If everything sent is to receive approbation, I fear the Council of the Royal Horticultural Society will suffer, as I thought they welcomed exhibits to the meetings; and, as in all exhibitions, some exhibits must be old, others not interesting to everyone. As to the appointment of sub-committees at Chiswick, I am aware, in a sense, they are not yet appointed. I do not object to a representative committee, but I do object to, say, three or four members granting Certificates, if these Certificates are not to be confirmed by a full committee at Westminster. It may happen—indeed, it has been the case this year—during the holiday season, that only a few members attend Chiswick; if so, I do not see why they should object to the full committee confirming the Certificates. This is the point my critic should keep to. On the other hand, he enters into personalities when he refers to my adjudicating upon exhibits sent by my brother gardener from Albury, and *vice versa*. Let me ask him if there is not a closer relationship in the composition of the committees—is there not such a thing as two brothers, or father and son? so that the Council must take these interesting facts into consideration. I consider the postscript he finishes with of little value, as of the nineteen gardeners on the committee, half live at such distances that they cannot attend, and the gardeners are always in a minority. It is not the composition of the committee, but the conduct of one of its members who attacks another anonymously that I object to. *G. Wythes.* [Enough has now been said on this question. En.]

BIRCHLEAVES.

Our illustration (p. 441) represents a new place recently laid out by Mr. Baines for Herbert Groves, Esq., at Birchleaves, near Weymouth. It lays to the south, and well out of the town, from whence the ground rises considerably until it reaches the highest point, where there is a broad stretch of comparatively level surface running east and west, high above Portland Roads, to which the foreshore, beginning at the dark line across the plan, descends rapidly to the water. The views from every part of

the grounds are amongst the most beautiful in the kingdom, especially from the higher portion surrounding the house; from this point the eye takes in the wide expanse of water, dotted with shipping, and the high chalk cliffs on the south and east, with the distant country beyond, including Portland Island.

Those acquainted with the locality will not require to be told that the western gales, to which the position is a good deal exposed, have necessitated care in the selection of the kinds of trees and shrubs to be used in the planting. In places such as the one in question, shelter is a matter of the first importance. In the most exposed positions, Austrian and Corsican Pines, *Pinus insignis* and *Cupressus macrocarpa*, have been freely introduced, so as to break the force of the blast from things less able to bear it. The planting on the foreshore is mostly confined to large masses of one kind of shrub in each clump, such as the green, the golden, and the silver variegated forms of *Euonymus*, Sea Buckthorn, lacinate-leaved Bramble, Double Gorse, and others of like character, with a few Pines interspersed amongst them to break the otherwise too even surface.

SCOTLAND.

CRYPTOGAMIC SOCIETY OF SCOTLAND.

THIS Society held its eighteenth annual Conference at Aberfoyle, on the 20th and 21st ult., under the presidency of Colonel Stirling, of Gargunnoch.

Aberfoyle is familiar to readers of *Rob Roy*. It is no longer, however, the Clachan of the romance. A large and spacious hotel now furnishes visitors with every modern comfort, while shops and villas are rapidly robbing the neighbourhood of the delights of its earlier seclusion. The hotel is at some distance from the original Clachan, but an effort is made to claim its romantic associations by hanging on an old tree a plough-coultter with the point painted red (shade of Scott!), to represent the red-hot implement with which Baillie Nicol Jarvie singed the Highlanders' plaid in Jean McAlpine's public-house. The traditions of the place are in exact accordance with the descriptions of Sir Walter Scott. The Clachan is on the opposite side of the "infant Forth," which is here crossed by "an old-fashioned stone bridge," and is situated beside the ruins of the old church, about half-a-mile distant from the present hotel. A venerable Ash tree is still pointed out as marking the site of the public-house, which was frequented by the famous outlaw, and a few rude stones still remain to mark its foundations. The various descriptions in *Rob Roy* of the scenery in the neighbourhood of the Clachan of Aberfoyle, are so wonderfully faithful and graphic that we involuntarily people the place with the imaginary characters of the novel.

The Conference was pretty well attended, and a delightful surprise awaited the members, in the arrival of Dr. Braithwaite, of London, a corresponding member of the Society, with whose fame they were familiar, but whom they had not previously had the pleasure of welcoming to Scotland. After a stormy period, the weather was all that could be desired during these days. The change was so welcome that the hotel-keeper wished we had come a month ago.

On the 20th, an excursion was made to Loch Ard, which lies in the pass between the valley of Aberfoyle and the Western Highlands. The scene is one of great natural beauty. "A profusion of thickets, knolls, and crags" surround the loch. Its shores are fringed by natural forests of Birch, Mountain Ash, and Oak, which clothe to varied heights the high hills, whose rugged summits rise out of the greenwood of the pass beneath. At many points of the rocky promontories and bays which indent its shores the trees overhang the water, and the coral berries of the Rowan are reflected in the mirror of its crystal depths. Its western extremity is closed in by more imposing mountains, the towering peak of Ben Lomond forming the distant background. Boats

FIG. 71.—PLAN OF A GARDEN AT BIRCHLEAVES, NEAR WEYMOUTH. (SEE P. 440.)

were hired for the day, that the party might select the most favourable ground along the shores. After passing underneath the rock, where the skirmish in which the English soldiers were defeated by the Highlanders took place, where Bailie Nicol Jarvie was "hung up between heaven and earth, like an auld Potato-bogle," and where the craven Morris was, at the command of Helen McGregor, bound, and hurled headlong into the loch. About an hour's rowing brought us to our hunting-ground. The sun was dipping behind Ben Lomond ere we quitted the scene, and twilight was deepening on the Avondu when we reached Aberfoyle.

The business meeting of the Society was held in the evening. The report of a committee appointed to consider the extension of the Society's work formed the chief subject of discussion. A revised map of Scotland, for geographical distribution, was adopted, along with a scheme for the more detailed record of species. Other proposals, having reference to publication, &c., were remitted to the committee. An increase of the Society's membership would greatly facilitate the accomplishment of its aims. The Secretary, in the absence of Mr. A. Stephen Wilson, of Aberdeen, read a short communication on "Potato Disease." Mr. Wilson continues to advocate the theory "that the disease arises from granules of mucoplasm distributed through all parts of the plant, and that there is no translocation of mycelium." The President then delivered the annual address, in which he dwelt upon the aims which the Society should keep in view. A cordial vote of thanks was accorded to him for his address and genial conduct of the meeting.

On Wednesday, the 21st, an excursion was made to the woods of Gartmore, the property of Mr. Cunningham Grahame, where a pleasant day was spent. As many of the members were obliged to leave on the following day, the Conference was brought to a close in the evening by the annual dinner.

The season, on the whole, has proved an unfruitful one, and few varieties were met with. Among mosses gathered during the excursions, may be mentioned—*Dicranum Scottianum*, Turner; *Hypnum callichroum*, Hsch.; *Hypnum crista-castrensis*, Linn.; and *Grimmia Stirtoni*, Schimper. The Lichen flora of Aberfoyle seems singularly meagre: the following may be noted—*Parmelia pertusa*, Schrank; *P. saxatilis* var. *sulcata*, Taylor, in fruit; and *Sphaerophoron compressum*, Ach., in fine fruit. Fungi were not numerous; although a good many species were recorded, none more uncommon than *Hygrophorus calyptrafermis*, B. and Br.; *Polyporus sulphureus*, Fr.; and *Rhizina undulata*, Fr., were met with. The specimens of the latter were very large, and finely developed. Beautiful specimens of *Chlorosplenium aruginosum* "Flo. Dan." (*Helotium aruginosum*, Fr.), were found growing on Birch; it is usually found on Oak.

Since the above was written, Mr. Phillips has reported *Peziza majalis*, Fr., gathered during the Conference at Aberfoyle, as new to Britain.

The next annual Conference of the Society will be held at Moffat, *J. S., Glamis.*

SALE OF ORCHIDS IN GLASGOW.

Between four and five hundred lots of Orchids, the property of Messrs. J. Shuttleworth & Co., Heaton, Bradford, Yorks, and Park Road, Clapham, London, were exposed for sale in the auction rooms, 72, Renfield Street, Glasgow, on September 28. The list included choice *Cattleyas*, *Laelia grandis tenebrosa*, *Cypripedium Lathomianum* ×, *Oncidium Marshallianum*, *O. Rogersii*, *Odontoglossum Roezlii*, *Coelogyne Lowii*, *Phalenopsis Esmeralda*, and other good things, chiefly established plants, mostly small, but clean and healthy. Unfortunately, few Orchid buyers were present, the seductions of the moors and coast retreats yet keeping the majority of these out of town. Consequently, the sale fell rather flat, and prices ran low. The following quotations give a fair idea of the bidings: *Odontoglossum Roezlii*, nice plants, one or two breaks, and spikes opening, or in flower, 4s. to 5s. each; *Cypripedium Harrisonianum*, nice plants, 6s.; *Oncidium sarcodes*, in

flower, 4s.; *Cattleya Schofieldiana*, good plant, 20s.; *Odontoglossum crispum*, in flower, good spike and plant, 7s.; *Oncidium macranthum*, good spike, fine plant, 8s.; *O. Forbesii*, good plant and spike, 6s.; *Odontoglossum grande*, fine plants, with spikes opening, or open, good varieties, 7s.; *Oncidium incurvum*, four spikes, fine plant, 10s.; *Odontoglossum triumphans*, 7s.; *O. Pescatorei*, good plant, 6s.; *O. Edwardsii*, with fine spike, 9s.; *Cypripedium Lathomianum* ×, 40s.; *C. Elliottianum*, good plant, 18s.; *C. selligerum rubrum*, 18s.; *C. Mrs. Charles Canham*, fine plant, 14s.; *Oncidium crispum*, fine spike, 20s.; *Sophranitis grandiflora*, good plant, 2s. 9d.; *Dendrobium crassinode album*, four bulbs, one break, four and a half guineas.

SOCIETIES.

ROYAL HORTICULTURAL.

OCTOBER 4.—An excellent display was brought together at the Drill Hall, on the above date, including many Orchids—some novelties amongst them; a great quantity of Michaelmas Daisies in variety, but in the case of one exhibitor vastly past their prime; other hardy herbaceous plants as cut blooms and a considerable quantity of Apples, Pears, Plums, &c.

Floral Committee.

Present: W. Marshall, Esq. (chairman), Messrs. Jno. Laing, B. Wynne, R. Dean, R. Owen, H. Herbat, C. F. Bause, J. Walker, G. Phippen, J. Fraser, G. Nicholson, F. Ross, W. C. Leach, N. Davis, C. E. Pearson, C. J. Salter, W. Bain, C. Jeffries, H. B. Pöe, T. Baines, G. Paul, W. Goldring, C. T. Druery, W. Furze, and G. Gordon.

A very bright display was effected by the various collection of hardy perennials, &c., for which special prizes had been offered to amateurs, besides which there were several other interesting exhibits. For eighteen bunches hardy perennials, the Earl of Dysart, Ham House, Richmond (gr., G. Sage), was awarded a 1st prize. His specimens were good and fresh looking, especially considering the rough weather that has obtained of late. The most noteworthy species were *Pyrethrum uliginosum*, *Eryngium Oliverianum*, *Aster lavagatus*, *Rudbeckia Newmannii*, *Gypsophila paniculata*, *Erigeron speciosus*, and some varieties of *Helianthus*. W. E. Hall, Esq., Coker Court, Yeovil (gr., Mr. Hildley), was 1st for twelve bunches, with *Anemone japonica*, *Gladiolus racemosus* (Princess Clothilde), a very pretty variety; *Helenium Hoopesii*, *Phygelius capensis*, *Helianthus laetiflorus*, &c. Mr. James Gibson, The Oaks Gardens, Carshalton, was 2nd for eight bunches; Mr. James Hudson, Gunnersbury House, Acton, was 1st. He had a very fine specimen of *Aster hesperabicus*, *Pyrethrum lacustreum*, *Helianthus multiflorus*, *maximus*, &c. 2nd, Miss Debenham, St. Peters, St. Albans; which included *Sedum spectabile*, *Gaillardia grandiflora*, and *Solidago virginica*. Messrs. Barr & Son, Covent Garden, contributed a large collection of Asters, the most striking of which were *A. Amellus majus*, *A. novi-belgii* (Robert Parker), *A. n.-b. roseus*, and *A. n.-b. Janus*, a pretty white variety, and the distinct yellow *A. Linosyris* (Silver Banksian Medal). Messrs. E. D. Shuttleworth & Co., Fleet, Hants, likewise furnished an immense growth of Asters, &c., amongst which we noticed *Aster azureus*, *A. longifolius formosus*, a number of varieties of *A. novi-belgii*, *A. amethystinus*, the curious little *A. cordifolius*, and *A. c. var. major*; varieties of *A. Amellus*, *A. umbellatus*, &c. (Bronze Banksian Medal).

The Rev. W. Wilks, Shirley Vicarage, brought *Aster Jno. Wood*, *A. Madame Trevelyan*, *A. decorus*, and *A. Thompsoni*.

A very neat yellow Carnation, named Fry's Buttnhole, came from Mr. Geo. Fry, Lewisham; also two blooms of two seedling Fuchsias, of considerable merit.

Mr. Thos. S. Ware, Tottenham, staged a lovely group of *Nerines*, in eight varieties; *N. Piantii*, a good dark crimson; *N. amabilis*, pale pink; *N. excellens*, rose, with darker line running along centre of petals; *N. sarniensis*, a good dark variety; and *N. corusca major*, a very fine rich scarlet. Also two or three plants of the pretty dwarf *Iris alata*, and a group of Tree Carnations, which included some very choice varieties.

Mr. H. Elliott, Stourvale Nursery, Christchurch also had a few *Nerines* in very fine condition; *N.*

corusca major and *N. c. m. sarniensis*, a very good purplish-rose; *N. gracilis*, and *N. bella*, a pink one, described as new, likewise exhibiting several varying forms of *Dracaena australis*, viz., *D. Doucetti*, a narrow rigid-leaved graceful plant; *D. australis*, with narrow leaves; *D. a.*, with broader leaves; *D. a. rubra*, with leaves of more breadth than the other forms, of a bronzy-green colour, and reddish-brown midrib—a distinct fine variety, which received a First-class Certificate; *D. a. congesta nana* is an erect stiff form; *D. a. aurea striata*, *D. a. nobilis*, broad green pendent leaves.

Messrs. Pitcher & Manda, Hextable, exhibited a new white incurved *Chrysanthemum*, named *Geo. Savage*.

A handsome *Tacsonia* came from Mr. W. Smythe, gr., Basing Park, Alton. It is a very distinct variety, colour scarlet, and named *T. Smythiana* (First-class Certificate).

Mr. Anthony Waterer, Knap Hill Nursery, Woking, Surrey, had a group of *Pernettyas*, well berried, and a specimen of *Picea pungens argentea*, and two rather delicate little plants of *Retinospora filifera aurea* (Bronze Banksian Medal).

Messrs. J. Veitch & Son, Chelsea, obtained a First-class Certificate for *Hymenanthera crassifolia*, which was figured in the last issue of the *Gardeners' Chronicle*. The same firm showed a group of *Caryopteris mastacanthus*, taken from the open ground, and in full bloom. Also some very well grown specimens of *Amasonia punicea*, for which a Cultural Commendation was awarded. Messrs. Veitch likewise secured a First-class Certificate for *Rhododendron multicolor* var. *Neptune*. This is a very fine hybrid; flowers four to five on each corymb, of a deep scarlet colour. A collection of Veitch's hybrid *Streptocarpus* was charming; the various tints of which this plant seems capable appear to be unlimited.

Messrs. B. S. Williams & Son, Upper Holloway, exhibit a new *Cliveia*, *Autumn Beauty*.

From Mr. C. Leach, gr. to the Duke of Northumberland, Albury Park, came some shoots of *Hippophae rhamnoides*, the very ornamental *Sea Buckthorn*, *Rosa rugosa*, and others. Also some well-grown specimens of *Mignonette Her Majesty*, in 32s.

Mr. W. Wells, Earlswood Nurseries, a good collection of *Chrysanthemum* blooms, including especially large blooms (for the season) of *Jeanne d'Arc*, some good blooms of a yellow variety, called *William Wells*; and many others of the large-flowering section, beside a number of single and semi-single varieties (Bronze Banksian Medal).

Mr. Richard Owen, Castle Hill Nursery, Maidenhead, showed the English-raised Seedling *Chrysanthemum Lady Brooke*, a reflexed Japanese, of canary-yellow, rather deeper in tint in the centre; *C. Madame Zephyr*, an early yellow-flowered variety; *C. General Hawkes* is a crimson reflexed Japanese, with thread florets.

Mr. Thomas Hobbs, St. Mark's Road, Bristol, sent a large double *Dahlia*, called *James Hobbs*.

Mr. John Crook, gr. to W. H. Evans, Esq., Forde Abbey, Chard, Somerset, sent a collection of Asters.

Messrs. John Laing & Son, Forest Hill, had a number of plants of the elegant little *Saxifraga sarmentosa tricolor superba*.

From Messrs. H. Cannell & Sons, Swanley, came some very fine blooms of zonal *Pelargoniums*, and some good blooms of *Begonia Rosebud*.

An Award of Merit was granted to *Dahlia Mrs. Vagg*, shown by Mr. Rawlings; and to *Chrysanthemum General Hawkes*, and *C. Lady Brook*, shown by Mr. Owen of Maidenhead.

Orchid Committee.

Present: Harry J. Veitch, Esq., in the Chair: and Messrs. Jas. O'Brien, Sec., Dr. Maxwell T. Masters, F.R.S., Sydney Courtauld, T. B. Haywood, F. Sander, Hugh Low and H. Williams.

The chief features of the meeting were the groups of Orchids, and of these the largest was contributed by Messrs. B. S. Williams & Son, Victoria and Paradise Nurseries, Upper Holloway, and which contained many rare species; the plants moreover were very tastefully set up. Among them were two fine forms of *Cypripedium Morganii* ×, *C. Euryandrum* ×, *C. vexillarium superbum* ×, *C. Ashburtonia superbum* ×, *C. Adonis* ×, *C. lo grande* ×, and many other *Cypripediums*. *Miltonia candida grandiflora*, with fifty flowers; *Oncidium incurvum album*, *Dendrobium Dearei*, *Lycaste lanipes*, &c. (Silver Flora Medal). Messrs. F. Sander & Co. also staged a group which was characterized, as usual, by the large proportion of fine and well-grown plants. Included were two

very handsome *Houlletia Brockleburiana*; many *Dendrobium Phalaenopsis Schroberianum*; a new hybrid *Calanthe*—*C. orphanum* ×, flowers white with yellow lip and purple eye; *Cypripedium Donatium* ×, *C. Brumanum* × (*Leeanum* × *anatum superbum*), *Oncidium Burbidgianum*; *Paphinia cristata grandis*, a charming pan of *Phalaenopsis Lowii*, the singular and pretty *Grobya Amherstiae*, *Sarcanthus teretifolius*, *Cattleyas*, &c. (Silver Banksian Medal).

The group set up by Messrs. Hugh Low & Co., of Clapton, was bright with plants of *Vanda Kimballiana*, *Vanda cœrulea* and *Cattleyas*, and also contained the rare white *Trichopilia rostrata*, *Cypripedium Schroderæ* ×, several *C. Parisbii* and *C. belatulum* (Silver Banksian Medal).

Messrs. Pitcher & Manda, The United States Nurseries, Hextable, Swanley, Kent, staged a small group of *Cypripediums*, chiefly hybrids, and very interesting for the facilities they offered for comparison (Vote of Thanks). Thos. Statter, Esq., Stand Hall, Whitefield, Manchester, exhibited a broad-petalled, nearly unspotted *C. granulosa*, a cut-spike of *Lælia elegans Chelsoniensis*, and a plant of a very singular form of *Cattleya bicolor* with a slate-blue lip, named *C. b. cœrulea*. W. C. Clark, Esq., Orleans House, Aigburth Drive, Liverpool, sent a fine drawing of a magnificent plant of *Cattleya Hardyana*, which flowered with Reginald Young, Esq. The drawing was made by Mrs. Clark, and the fine plant was procured unflowered from one of Messrs. Sander's importations. The plant had ten flowers. C. K. Wild, Esq. Hampstead (gr., Mr. R. Pallant), exhibited *Stanhopea Wardii aurea*.

Wilberforce Bryant, Esq., Stoke Park, Slough (gr., Mr. David Kemp), sent a fine plant of *Oncidium orthorhynchum*, with forty-five spikes (Cultural Commendation); and W. Wells, Esq., Broomfield, Sale, near Manchester (gr., Wm. R. Hinde), sent a flower of a richly-coloured *Cattleya* of the *C. Hardyana* class, but with sepals and petals marbled cream-colour and rose, and resembling the beautiful form described in our columns from Lord Rothschild's collection as *C. aurea marmorata*.

Fruit and Vegetable Committee.

Present: P. Crowley, Esq., Chairman; Messrs. J. Lee, T. F. Rivers, W. Wilks, H. Veitch, G. W. Cummins, J. Cheal, G. Taber, G. Bunyard, J. Wright, A. Dean, W. Bates, G. H. Sage, G. Wythes, C. Ross, J. Hudson, H. Balderson, R. Hogg, Harrison Weir, and J. Willard.

The exhibits under this committee included a large number of Apples and some Pears, both nurserymen and amateurs contributing their quota to the display.

From the Royal Horticultural Society's Gardens, Chiswick, were exhibited several kinds of Grapes, including *Gros Colmar*, in good condition; a white variety called *White Gros Colmar* (First-class Certificate). Another white Grape called *Chasselas Vibert*, grown in a cool house, which obtained an Award of Merit, but the flavour of which did not commend itself to us, and *Royal Muscadine* from a cool house. Also two dishes of a fine-looking *Apple King Harry*, which obtained an Award of Merit.

Mr. A. J. Brown, School of Handicraft, Chertsey, sent a very nice collection of Apples and Pears, which had been grown from cordons, planted late in 1890.

From Mr. J. Crook, Forde Abbey, came *Plams Coe's Golden Drop* and *Reine Claude de Bay*, one dish of each, and a few Apples (Vote of Thanks).

Two seedling Apples came from Messrs. Stephen Spooner & Sons, Hounslow Nurseries, The Baron and another one called *Richmond Seedling*. Another seedling Apple, called the *Empress*, was from Mr. G. Edmunds, The Grange, Gillingham. Mr. J. Miles, Normandy Farm, Erith, sent a good dish of *Apple Duchess of Kent*.

Mr. Chas. Ross, gr. to Col. Archer, Welford Park, Newbury, obtained an Award of Merit for No. 2 Seedling Apple from *Golden Reinette*; he also showed another seedling from the same variety. A Seedling Melon of considerable merit, obtained from Read's Scarlet Flesh, and *Hero of Locking*, was from Dr. Frankland (gr., Chas. Kitchings). A first-class Apple called *Rivers' Codlin*, of good appearance and fair size, was shown by Messrs. T. F. Rivers & Son, Sawbridgeworth, and was awarded a First-class Certificate.

Dowager Lady Freak, Fulwell Park, Twickenham (gr., Mr. Rickwood), received a Silver-gilt Knighting Medal for a good collection of Apples and Pears. Amongst which we noticed Apples, *King of Pippin*, *Cox's Orange Pippin* (very large), and *Frogmore Prolific*, as being particularly good. Among the Pears were *Beurré Clairgeau*, *Louise Bonne of Jersey*,

Jersey Gratioli, and *Durondeau*, all of which were ready for table. Another good collection of Apples came from A. H. Smee, Esq., The Grange, Carshalton (gr., Mr. Cummins). The following were very fine:—*Dutch Codlin*, *Bismarck*, *Beauty of Wilts*, *Farmer's Seedling*, *Worcester Pearmain*, *Yorkshire Beauty*, *Manx Codlin*, *Gascoyne's Scarlet*, *Buckley's Seedling*, &c. (A Silver Knighting Medal was awarded.)

Messrs. J. Cheal & Sons, The Nurseries, Crawley, staged the largest collection of Apples and Pears, and included some very fine fruits. Of Pears, *Beurré Superfin*, *Louise Bonne of Jersey*, *Pitmaston Duchess*, *King Edward*, *Bon Vicar*, and *Princess* were good and ripe. Amongst Apples, particularly noticeable were *Duchess of Oldenburg*, *Lewes's Incomparable*, *Beauty of Kent*, *Worcester Pearmain*, *The Queen*, *Ackera*, *Emperor Alexander*, *Peasgood's Nonsuch*, *Hollandbury*, *Cellini Pippin*, *Lady Sudeley*, and *Mabbot's Pearmain* (Silver Banksian Medal).

Mr. J. Willard, Holly Lodge Gardens, Highgate, sent fruits cooked and uncooked of a *Maize* called *Adams' Early*. They were of exceptionally good flavour, and were voted an Award of Merit. The following particulars accompanied the heads. Two sowings were made, one on April 15, and another on May 20, in an open border. The Cobs have been used regularly for the table since August 1.

Tomato, *Ham Green Favourite*, came from Mr. Jas. Hudson, Gunnersbury House, Acton. The fruits which were of much merit, had been grown in a bed of ashes. Mr. Robt. Owen, Maidenhead, showed a dish of fairly good *Tomatos*, called *Owen's Perfection*. Another dish of *Tomatos* came from Mr. J. Simpson, Dollis Hill, Kilburn.

Mr. John Wilson, Glenlee Gardens, Hamilton, showed a very large seedling *Cucumber*.

LECTURE ON MICHAELMAS DAISIES.

In the afternoon a lecture on the above subject was given by Mr. D. Dewar, of the Royal Garden, Kew. In commencing, the lecturer referred to the collection at Chiswick, and said he believed it to be the finest collection extant. The committee of the Royal Horticultural Society were submitting the collection to the fullest review possible, and correcting the classification and nomenclature as far as possible. There were many which Mr. Dewar believed to be of garden origin, and these were giving the committee a great amount of trouble. He preferred to have little to say upon these varieties pending the issue of the report of the committee, so that confusion through the possible altering of some of the names might be avoided; and Mr. Dewar hoped that when these were dealt with, and permanent names attached to them that they would receive English names, that they might be readily distinguishable from the natural species.

The number of the cultivated species known to botanists was roundly speaking about 250, and of these some 140 are natives of the United States of America. It is from the Eastern United States that most of the species useful to cultivators have come. Mr. Dewar said that anything that tended to draw together autumn and spring should be welcome to our gardens, and the decorative value of the *Michaelmas Daisy* being so well known, ought to ensure them a kindly reception, besides which they formed an interesting feature in the flower garden and pleasure grounds. Some of the *Asters* might be used as bedding plants, and the dull beds of *Rhododendrons* and other evergreens would be made ornamental, if they were judiciously thinned out, and some of the more suitable of the *Asters* planted in clumps. *Asters* liked a strong, rich, deep loam, and on the whole enjoyed lifting and division every year. When division is effected, the outside crowns should be used for planting (as these are the strongest), and the centre broken up or thrown away. This should be done in the spring, just as they were commencing to grow. They might also be raised from seed, which would be found to be a very interesting process. The lecturer said that many of the species were worthy of being planted in beds by themselves, that their better quality might show to advantage. Mr. Dewar afterwards gave a review of the genus, and enumerated some of the species that he thought most worthy of cultivation, at the same time giving directions as to each, and the time at which they might be expected to flower. The lecturer, in concluding, advised all who were interested in these plants, to go to Chiswick, and make a selection for themselves. The result of the work of the committee in regard to that collection would be published as soon as possible. Dr. Masters, who

occupied the chair, said the difficulties experienced with the genus were due to the fact, that the genus was now in process of formation, and botanists, as a result, were frequently confronted with new forms, many of which in course of time would die out, when the task of discrimination would be easier.

CHISWICK CERTIFICATES.

We are requested to publish the following Minute of Council:—

"The attention of the Council having been drawn to a difficulty in the awarding of Certificates, &c., to plants which have received three marks (xxx) at Chiswick, passed the following minute:—

"The Council request that in future, whenever any plant (fruit, flower, seed, vegetable, &c.) shall have had xxx given it by a committee meeting at Chiswick, the Superintendent of the Gardens will (if it be possible) bring it forward at the next (or nearest possible) general meeting of the Society, at Westminster, or elsewhere, in order that it may, if still thought deserving, receive a more definite award."

The Council also passed the following minute:—

"The definite award made under the above minute of Council will be given (as all the Society's awards are made) to the plant in question, and the custody of the Certificate or other award will vest in the person sending the plant, &c., to Chiswick for trial. W. Wilks, Sec. R.H.S."

INTERNATIONAL SHOW.

HARDY FRUITS AND POTATOS.

The show of hardy fruits and Potatos in connection with the International Horticultural Exhibition at Earl's Court was a complete success. The classes were so competed for that the available space proved totally insufficient for the occasion, and this minimised to a large extent the area devoted to the non-competitive exhibits. In the first class for fruits there were five competitors, and the number of dishes staged was 500. The prize was for a collection of Apples, kitchen and dessert, six fruits of each variety, not to exceed 100 dishes, distinct. The most successful exhibitors were Messrs. Geo. Bunyard & Co., Maidstone, who staged a magnificent collection of varieties, the number of which were far too many for us to notice, suffice to say that *Bismarck* was staged as well as it ever has been, and some specimens of *Stone's Apple* weighed 20 oz. each. The English Fruit and Rose Company, Hereford, were 2nd, with a collection that in any ordinary competition would have been 1st; Mr. Jno. Scott, The Royal Nurseries, Merriott, Crewkerne, was 3rd.

For a collection of Pears, to consist of six fruits of each variety, to the extent of fifty dishes, Mr. H. Becker, Jersey, was 1st, the collection contained some very large fruits, but there were several dishes that were rather weak; 2nd, Mr. G. Woodward, Barham Court Gardens; and Mr. A. J. Thomas, Rodmersham, near Sittingbourne, was 3rd.

The next class was for a trophy of vegetables arranged for effect. The 1st prize fell to Mr. W. Pope, Newbury, whose collection could not fail to arrest attention; particularly good were the Carrots, Beets, and other roots. Mr. J. Gibson, Carshalton, was 2nd.

All the other classes for fruit were open only to amateurs. For a collection of Apples, kitchen and dessert, fifty dishes, distinct, six fruits each, the 1st prize was secured by Mr. Geo. Woodward, Barham Court Gardens, Maidstone, with fine and well-coloured fruits; Mr. Thomas Turton, Reading, was 2nd; and the 3rd prize went to Mr. Geo. Goldsmith, gr. to Sir E. D. Loder, Bart., Horsham.

For twenty-four dishes, the successful exhibitor was Mr. Jno. McKensie, Linton Park, Maidstone; 2nd, Mr. F. Smith, Loddington, Maidstone; and 3rd, Mr. Thos. Turton, Reading.

In the competition for twelve dishes, Mr. George Woodward was 1st, Mr. Austen T. Killick 2nd, and Mr. George Chambers, Maidstone, 3rd.

For twelve dishes of Pears, distinct, the 1st prize went to Mr. George Goldsmith, gr. to Sir E. G. Loder, Bart., Horsham, who had *Louise Bonne of Jersey* in perfect condition, and *Marie Louise*, a very good colour, and clean; 2nd, Mr. A. Offer, Crawley; 3rd, Mr. J. Nicholson, Chingford.

Mr. R. Smith, gr. to Lady Francis Fletcher, Yalding, Kent, was 1st for six dishes; Mr. C. West, Landford, Salisbury, 2nd; and Mr. T. G. Dean, gr. to Hon. C. Leveson Gower, Titsey Place, Limpsfield, 3rd.

For twelve dishes of vegetables, not to contain more than two dishes of any one kind, the 1st prize was secured by Mr. Thomas Wilkins, gr. to Lady Theodora Guest, Inwood House, Hensbridge; Mr.

Richard Lye was 2nd, and Mr. J. Friend, gr. to the Hon. P. C. Glyn, Rooksnest, Godstone, 3rd.

For a collection of Sunflowers, Messrs. Barr & Son, Covent Garden, were 1st, and Mr. G. H. Sage, The Gardens, Ham House, Richmond, 2nd. Mr. Norman Davis, Lilford Road Nurseries, Camberwell, was 1st for a collection of Michaelmas Daisies, Messrs. Barr & Son, 2nd., and Mr. Geo. H. Sage, 3rd.

Potatos.—Class I. was for twelve dishes, distinct varieties, each dish to contain nine tubers. The 1st place was secured by Mr. J. H. Ridgewell, Cambridge, who showed Snowdrop, Mr. Breese, Fidler's Reading Giant, Sutton's Satisfaction, Queen of the Valley, Edgocate Purple, Pink Perfection, The Dean, Come to Stay, Beauty of Hebron, Perfect Peach Bloom, Lord Tennyson. 2nd, Mr. Wm. Pope, Newbury; and 3rd, Mr. A. Cross, Shutford, Banbury. For nine dishes, Mr. James Simkins, Shillington, near Hitchin, was 1st, who staged Sutton's Seedling, Chancellor, Sutton's Satisfaction, The Dean, Fidler's Reading Giant, Pink Perfection, Snowdrop, Sutton's Reading Ruby, and Sutton's Best of All; Mr. Wm. Pope, Newbury, was 2nd; and Mr. Arthur Coomes, Dudley, 3rd.

For six dishes, the successful exhibitor was Mr. Jas. Simkins, Shillington; Mr. Wm. Pope, Newbury, 2nd; and Mr. J. H. Ridgewell, 3rd.

For three dishes of coloured round Potatos, Mr. J. H. Ridgewell was 1st again, with Reading Russet, Vicar of Laleham, and Pink Perfection.

Mr. Jas. Lye was 1st for three dishes of white kidney, and Mr. J. Ridgewell 2nd, with Snowdrop, Fidler's Purity, and Reading Giant.

For three dishes of kidneys (coloured), Mr. Ridgewell was 1st, with Mr. Breese, Edgocate Purple, and White Elephant; 2nd, Mr. G. North, Buckingham; and 3rd, Mr. G. Galt, Oxford.

There were numerous competitors for the best dish of any white round Potato, and the London Hero, shown by Mr. T. Wilkins, gr. to Lady Theodora Guest, was exceptionally fine; Mr. James Simkins, Shillington, was 2nd; and Mr. J. Ridgewell, 3rd.

For the best dish of any coloured round, Mr. James Simkins contended successfully with The Dean; Mr. R. Lye, gr. to W. H. Kingsmill, Esq., Newbury, who was 2nd, showing Reading Russet; Purple Perfection won the 3rd position for Mr. G. Galt, Oxford.

Mr. J. H. Ridgewell had the best dish of any white kidney, in Snowdrop, and Mr. Tom Tooley, 22, Albert Street, Banbury, the best coloured kidney, in Mr. Breese.

For six dishes of Potatos, distinct varieties, introduced since January 1, 1886, the 1st prize went to Mr. James Simkins, Shillington, for good dishes of Reliance, Sutton's Abundance, Sutton's Seedling, Sutton's Windsor Castle, Sutton's Satisfaction, and Fidler's Reading Giant; Mr. J. H. Ridgewell was 2nd, and Mr. James Lye, Market Lavington, 3rd.

For three dishes under same conditions, Mr. J. H. Ridgewell was 1st, with Fidler's Reading Giant, Pink Perfection, and Sutton's Satisfaction; Mr. Tom Tooley was 2nd, and Mr. E. S. Wiles, Edith Road, Oxford, 3rd.

Certificates were awarded to seedling varieties of Potatos, of sufficient merit, not in commerce, as under:—For single dish of white round, First-class Certificates were awarded to Mr. F. Laxton, Bedford, for Murphy, obtained from Scotch Champion and Reading Hero; to Mr. E. S. Wiles, Edith Road, Oxford, for Oxford Surprise, from Chancellor and Sutton's Abundance; and to Mr. Charles Ross, Welford Park, Newbury, for his Recruit.

For a dish of coloured round Potatos, First-class Certificates were awarded to Mr. E. S. Wiles, Edith Road, Oxford, for his Pink-eyed Perfection from Sutton's Abundance × Reading Russet, and to Mr. Horam Fletcher, Annesley, Notts, for a dish of Lillie Langtry, obtained from naturally-fertilised seed from Lord Tennyson.

For a single dish of white kidney, the following obtained Certificates:—Rising Star, by Mr. Chas. Ross, Welford Park; Lord Wolseley, by Mr. C. W. Howard, Canterbury, and Oxford Giant, by Mr. E. S. Wiles. For a single dish of coloured kidney Potato, Mr. W. Kerr, Darganel, Dumfries, obtained a Certificate for a good-looking variety, said to be a seedling from Abundance.

Non-competitive exhibits occupied a very large amount of space, and added considerably to the general display. Messrs. Jas. Veitch & Son, Chelsea, showed a magnificent collection of fruits, including all the kinds now in season, and staged in first-class style (Gold Medal). Messrs. T. F. Rivers & Son, Sawbridgeworth, had some well-fruited trees in pots, and some very fine fruits of Pears and Apples; also three particularly good bunches of Grapes, Black Alicante

(Gold Medal). Messrs. J. Cheal & Son, Crawley, were awarded a Silver-gilt Medal for a collection of Apples, Pears, Grapes, &c.; and Mr. Geo. Woodward, Barham Court, Maidstone, for a collection of remarkably good Peaches and Pears from the open air (a Silver Gilt Medal). Mr. Geo. Reynolds, gr. to Messrs. Rothschild, Acton, had a collection of Melons, and obtained a Silver Medal. Messrs. Geo. Bunyard & Co. also exhibited a collection of Apples and Pears in their usual style (Silver-gilt Medal). Mr. W. Iceton, Putney Park Lane, for a good quantity of well-finished Grapes, Gros Colmar, was awarded a Silver Medal. Mr. S. T. Wright, The Gardens, Gleastons Court, Ross, nine bunches of Black Alicante Grapes, very fine (Silver Medal). Mr. Joo. Watkins, Pomona Farm, Hereford, a large collection of fruit, including some cider, and ornamental Crab Apples (Silver Medal). Mr. H. Becker, Jersey, some very fine Pears (Silver Medal). Messrs. S. Spooner & Sons, Hounslow, collection of Apples (Silver Medal). Messrs. Jarman & Co., Chard, Somerset, a collection of fruit and Onions (Silver Medal); also First-class Certificate for a new and distinct Onion, Somerset Hero. Messrs. H. Lane & Son, Berkhamstead, a collection of Apples and Nuts (Silver Medal). Messrs. Chas. Lee & Son, Hammersmith, one hundred dishes of Apples (Silver-gilt Medal). The National Fruit Growers' League, St. Martin's House, Ludgate Hill, a collection of fruits (Bronze Medal). Mr. A. K. Rickwood, gr. to Lady Freake, Twickenham, forty dishes of Apples and Pears (Silver Medal). Mr. W. A. Trotter, gr. to F. Ricardo, Esq., Bromesberrow Place, Ledbury, exhibited a case of English hardy fruits that he had evaporated, including Apples, Pears, Plums, Damsons, French Beans, &c.; some were conserved as well as evaporated, and the whole were exceedingly interesting, and appeared to be of equal merit with those imported (Silver Medal). Messrs. J. Peed & Son, Streatam, one hundred dishes of Apples, &c. (Bronze Medal). Mr. R. Wells, Fruit Nurseries, Crawley, collection of Apples (Bronze Medal). Mr. Bytheway, Marlborough, twenty-five dishes of Apples (Bronze Medal). Mr. Ryder, Orpington, Kent, twenty-five distinct dishes of Tomatos (Silver Medal). Mr. W. Taylor, Hampton, forty dishes of Apples; Mr. J. Miller, gr. to Lord Foley, Ruxley Lodge, Esher, ninety dishes of Apples and Pears; Mr. J. Wallis, gr. to R. Sneyd, Esq., Keele Hall, Staffordshire, some fine Peaches and a dish of Figs (Medal). Messrs. Sutton & Sons, Reading, had an immense collection of Potatos and other dishes, which occupied two tables running the whole of the length of the annex. About 4500 tubers, in 222 varieties, were included, and upwards of eighty seedlings, not yet in commerce (Gold Medal). Mr. C. Fidler, Reading, had another very large collection of Potatos, including some extra large specimens of Fidler's Reading Giant (Silver Medal). Mr. H. Deverill, Banbury, had a stand of his English-grown Pedigree Onions (Silver Gilt Medal). Messrs. Harrison & Sons, Leicester, a collection of Potatos and other vegetables (Bronze Medal). Mr. Ed. Choppins, Melton, collection of Potatos (Silver-gilt Medal). Mr. W. Kerr, Dumfries, collection of Potatos (Silver Medal). Messrs. W. W. Johnson & Sons, Boston, collection of Potatos (Bronze Medal). Messrs. Vilmorin, Andrieux & Co., Paris, a collection of varieties of Celery, Endive, Dandelion, &c., of first-rate quality (Silver-gilt Medal).

Messrs. Jno. Laing & Son, Forest Hill, staged a group of Begonias, good for the season, but so clearly inferior to that staged on the last occasion, as to remind us vividly of the approaching winter (Mr. Laing has exhibited Begonias from April to October); also a collection of fruit (Gold Medal).

Mr. Chas. Turner, Slough, a collection of Helianthus, Asters, Anemones, &c. (Silver Medal).

Messrs. B. S. Williams & Son, Upper Holloway, a group of well-grown foliage plants, Crotons, &c. Mr. H. Wrede, Luneberg, Germany, a collection of Violas and Pansies (Silver Medal).

Messrs. E. D. Shuttleworth & Co., a group of herbaceous flowers, &c.; also a group of ornamental foliage plants (Silver Gilt Medal).

Messrs. H. Cannell & Sons, Swanley, blooms of Begonias and Pelargoniums (Bronze Medal). Mr. W. Wells, Earlswood, Redhill, collection of Chrysanthemum blooms (Bronze Medal). Mr. J. R. Chard, Stoke Newington, a table arranged for effect (Silver Medal). Messrs. Perkins & Sons, Coventry, some blooms of Cactus Dahlias, Matchless, a dark crimson variety, with petals having as good form as the old Juarezii, was awarded a First-class Certificate. Messrs. Barr &

Son, Covent Garden, a group of herbaceous flowers (Silver Medal). Messrs. W. Barron & Son, Borrowash, near Derby, cut sprays of ornamental trees and shrubs (Silver Medal). Mr. Geo. Wythes, gr. to the Duke of Northumberland, Syon House, staged a nice group of foliage plants and Chrysanthemums (Silver Medal). Messrs. Wm. Paul & Sons, Waltham Cross, a collection of Roses, Fruits, &c. (Silver-gilt Medal).

HEALING DISTRICT GARDENERS' MUTUAL IMPROVEMENT.

SEPTEMBER 27.—The annual meeting of this society was held on the evening of the above date, when the annual report and balance sheet were read, and the officers and committee appointed for the ensuing year. The report of the committee states that, although the balance in hands of treasurer is not quite so large as last year, the weekly meetings during the past year were well attended, and the papers read were up to the standard of excellence, and the exhibits by members at the weekly meetings far exceeded those of previous years. The society is greatly indebted to gentlemen residing in the neighbourhood for papers contributed, and prizes given for essays. The president is E. M. Nelson, Esq.; the chairman, G. F. Nixon, Esq. Papers for the coming session are promised by Messrs. G. Gordon, R. Dean, J. Hudson, G. Wythes, E. Cook, and others. Prizes for essays are offered by Mr. R. Dean, R. Dawes, Esq., and C. Jones, Esq.

DEVON AND EXETER GARDENERS' ASSOCIATION.

SEPTEMBER 28.—The annual meeting of the Devon and Exeter Gardeners' Association was held at the Guildhall, on the above date. The President, Mr. C. T. K. Roberts, presided. The Chairman said he thought they might congratulate themselves on the success which the Society had attained during last year; and he trusted it was but an augury of greater success. He had pleasure in moving that Mr. Lethbridge, of Courtlands, be elected as President for the ensuing year. Mr. A. Hope seconded the motion, which was carried unanimously. The following were elected Vice-Presidents of the Society:—Rev. Dr. Dangar, Rev. A. H. Cruwys, Major Tracey, Lieut. Smith, Mr. R. N. G. Baker, Mr. J. D. Cann, Mr. R. M. Daw, Mr. H. C. Lloyd, Mr. H. Michelmore, Mr. Ed. Sanders, Mr. T. M. Snow, Mr. H. D. Thomas, Mr. P. C. M. Veitch. Mr. Hope remarked that the excursion recently held was so successful that it would probably be held again next year. A programme had been drawn up for the session ending at Christmas. For the following Spring Session, Dr. Dangar had promised to read a paper on "Insects which are Destructive to Fruit Crops." The Society had made an application to the County Council for a grant towards promoting technical education in gardening. He had received a letter from the clerk to the County Council acknowledging the receipt of the application. Mr. Hope believed the Society had several good friends on the Council, who would assist them if possible. It was a much debated question whether the course which the Society suggested, namely, that of having lectures on gardening, was not exploded. That, however, was a matter for the consideration of the County Council. Whether the Society succeeded in getting the grant or not, it would certainly call attention to the Society as being the best medium for disseminating technical knowledge on horticultural subjects. At one of the Society Committee meetings a representation was made that some men were members who were not gardeners. They were railway men and others who had garden plots, which they worked themselves. The Committee thought it would be hard to exclude anyone who wished to join, and they decided to admit the men at the same rate as the gardeners. It had been suggested that a spring flower show should be held under the auspices of the Society next March, confined to members, and that no prizes should be given. They did not desire to enter into competition with any existing institution, such as the Devon and Exeter Horticultural Society, which they all wished to see flourishing. In the absence of Mr. Andrews, Mr. Bartlett moved that the show be held in March. The motion having been seconded, the Chairman thought that before deciding upon holding the show the members should have before them some details as to the probable expense. He did not wish to throw cold water on the idea, but it was certainly a matter that required great consideration before the

Society committed itself to it. On October 5, Mr. McCormick read a paper on "Grape Vines, and their Cultivation."

PRESTON FLORAL.

OCTOBER 1.—There was a large attendance at the first monthly competition in connection with the Preston and Fulwood Floral and Horticultural Society held on Saturday. There was a fine display of flowers and fruit. The 1st prize went to Lord Lathom's gardener, and the 2nd was carried off by Richard Frisby, gr. to Miss Harington. There were also prizes for the best bunch of Grapes. The winner of the 1st preferred to be anonymous, and the 2nd went to Lord Lathom. At the meeting held subsequently a paper on the "Cultivation of the Fuchsia" was read by Mr. Roberts, gr. to Mrs. Townley Parker, Cuerden Hall. The essayist traced the history of the flower in an interesting fashion, and gave some practical hints as to its cultivation. A hearty vote of thanks was accorded Mr. Roberts at the close. The display of fruit and flowers at the gathering was equal to many a show.

Obituary.

CHARLES HENRY SHARMAN.—We greatly regret to have to record the death, on Sept. 30, of Mr. Sharman in the fifty-first year of his age. Mr. Sharman had been for many years manager for Messrs. Jas. Carter & Co. of Holborn. His zeal and energy elicited respect, and his geniality inspired a feeling of warm regard among those with whom he came in contact. He was zealous not only in the service of his employers, but eager to promote the advance of horticulture and the welfare of its practitioners. Thus, in addition to the ordinary managerial duties in a large seed house, he had the direction of the nursery at Forest Hill, and of the trial grounds in connection with them. He was thoroughly imbued with the notion that the processes that the florist adopts for the improvement of flowers should be acted on in the amelioration of farm crops and of the produce of the market-garden. With this view he instituted and supervised those experiments on the cross-breeding of cereals which have been so successful, and it was only in a recent number that we had occasion to chronicle the success of the experiments carried out under his directions at Bromley with the view of testing the value of the copper-mixture in the prevention and mitigation of the Potato disease. Mr. Sharman had suffered from some brain affection for some time, and though he had partially recovered, his friends saw that his health had been seriously impaired. Though retaining much of his old brightness of manner, he was no longer capable of the prolonged exertion which he formerly thought light of. It is almost needless to say of so good-hearted a man, that he did not overlook the claims of the infirm and the helpless, and that he was an active worker for our horticultural charities. We believe that the very first cheque which was paid into the Gardeners' Orphan Fund on its institution came through his hands. With an expression of satisfaction he told us this circumstance on the last occasion when we saw him, and we do not think we can close our notice with a worthier tribute to his memory than to say that amid his busy career he thought of the sick and needy.

MR. WILLIAM STEELL, the well known nurseryman of Kew Road, Richmond, Surrey, passed away quietly on the afternoon of the 3rd inst., at the age of 78 years. Like his elder brother George, whom he only survived 15 months, he was born in Richmond and lived there all his life, and like him was a quiet, kindly and honourable man, highly respected by all his numerous friends and neighbours.

VARIORUM.

MR. JAY GOULD, the American millionaire, has a passion for horticulture, and at his country residence on the banks of the Hudson River he has a collection of plants and flowers which cost him

many hundreds of thousands of dollars. Mr. Gould has recently given an order to an American firm for an additional conservatory, the existing glass-houses being inadequate. The price to be paid for the new conservatory is estimated at 100,000 dols., equal in English money to about £20,000.

COTTON-SEED SUGAR.—Sugar from the Cotton plant would seem to be a thing scarcely to have been dreamt of, yet on the authority of a British trade journal, quoted in a recent report on the cultivation of Cotton in Zanzibar, we read the following:—"The latest reported discovery in connection with Cotton seed comes from Germany, where it is said a process has been discovered for extracting sugar from Cotton-seed meal; the sugar is of a superior grade, but cannot be sold in competition with the ordinary article. It is said to be inclined to ferment or sour, and hence better in use for preserving fruits. It is described as being fifteen times sweeter than cane sugar, and twenty times more so than sugar made from Beets." Another use to which Cotton seed has recently been found applicable is for making felt from the lint which clings to the seed after it has gone through the "gin." The cloth, it is said, will come into wide use for hats, &c., as the process is inexpensive, and the material has hitherto been counted waste.

THE GINGER BEER PLANT.

PROF. MARSHALL WARD has made an elaborate study of the "substance or structure popularly known in many parts of the country as the ginger-beer plant, from its association with the domestic manufacture of the well-known summer beverage so often purchased in villages and towns in various parts of the British Isles, where it is usually put up in brown stone bottles with tied corks"! It can hardly be supposed that even the Fellows of the Royal Society are ignorant of these facts, so it must be concluded that the passage in question is intended for the intelligent foreign reader of the *Philosophical Transactions*. The general nature of the substance, and its use in effecting the fermentation of saccharine solutions to which ginger has been added, have long been known, but no definite knowledge of the plant had been obtained, and curiously enough no record of its history and introduction into this country. Professor Ward, with infinite patience, has succeeded in showing that the "plant" is really a compound of a yeast and of a bacterium. These are mixed with other organisms, so that to ascertain what was the office of each, somewhere about two thousand cultures, each extending over periods varying from a few days to two years, had to be undertaken. Of these numerous organisms two only are essential to the constitution of the ginger-beer plant, the rest being adventitiously present. The one organism is a mould such as appears in sour beer, the other the bacterium which forms the principal constituent of the vinegar-plant. Essential or adventitious, the organisms were isolated, cultivated and experimented upon with great care and thoroughness, so that the whole research was one of the greatest scientific importance. The results are rendered certain by the circumstance that Professor WARD has not only investigated the life-history of each organism singly, but by synthetic methods, bringing together the yeast and the bacterium, has succeeded in producing the ginger-beer plant. The yeast is probably derived from the sugar, the bacterium from the ginger. The study of the "symbiotic fermentations" occasioned by these organisms, is one of extreme importance in reference to many epidemic diseases, so that Professor Ward may be congratulated on what he has accomplished as a physiologist, and for the probable bearing of his researches on the progress of our knowledge of many diseases.

THE WEATHER.

[By the term "accumulated temperature" is meant the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named; and this combined result is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

The districts indicated by number in the first column are the following:—
0, Scotland, N. Principal Wheat-producing Districts—1, Scotland, E.; 2, England, N.E.; 3, England, E.; 4, Midland Counties; 5, England, S.
Principal Grazing, &c., Districts—6, Scotland, W.; 7, England, N.W.; 8, England, S.W.; 9, Ireland, N.; 10, Ireland, S.; (* Channel Islands.)

THE PAST WEEK.

THE following summary record of the weather for the week ending October 1, is furnished from the Meteorological Office:—

"The weather during this week has become cold, wet, and very unsettled, and the air raw; sharp ground frosts have occurred at times. Thunderstorms have occurred very frequently, and in almost all parts of the Kingdom.

"The temperature has been below its mean value in all districts, excepting 'England, S.' and the 'Channel Islands;' the deficiency being greatest in Scotland and Ireland, where it ranged from 2° to 3°. The highest of the maxima occurred during the first three days, and ranged from only 58° in 'Scotland, N.,' to 64° or 65° in the north of England, and to 68° over our Midland, Eastern, and Southern counties. The lowest of the minima occurred on Friday or Saturday, when the thermometer went down to 28° in 'Scotland, E.,' 30° in 'Scotland, N.,' and 33° over our 'Midland Counties' and 'England, S.W.' In the 'Channel Islands,' however, the minimum was only 48°.

"The rainfall was in excess everywhere; in 'England, S.W.,' the excess was 1.2 inch; in 'Scotland, W.,' 1.0 inch, and in 'Scotland, N.,' 'England, N.W.,' and the 'Channel Islands,' 0.8 inch; while in 'England, N.E.,' the excess was only 0.1 inch.

"The bright sunshine was in excess of the mean over Ireland and the North-eastern, Eastern, and Midland parts of Great Britain, but slightly deficient elsewhere. The largest number of hours recorded were 34 in 'Ireland, S.,' and 33 in 'England, E.,' while the smallest were 12 in 'Scotland, N.,' The greatest excess was 9 hours in 'Ireland, S.,' while the greatest deficiency was 6 to 7 hours in the southern and south-western parts of England."

PROFESSOR HUXLEY is the hero of more witty stories than any other living man of science, and when somebody puts together a good Huxleyana, the world's stock of cheerfulness will be considerably increased. A fairly good story is handed down by his students, which records an answer he gave to one of them who made the following inquiry:—"May I ask, sir, what is the best book on comparative anatomy?" "There isn't one," was the Professor's reply. "But," remarked the astonished student, "you have written one yourself." "True, and it's as bad as the others."

MARKETS.

COVENT GARDEN, October 6.

[We cannot accept any editorial responsibility for the subjoined reports. They are furnished to us regularly every Thursday, by the kindness of several of the principal salesmen, who revise the list, and who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the supply in the market, and the demand; and they fluctuate, not only from day to day, but often several times in one day. Ed.]

TRADE DULL. Cobba easier. James Webber, Wholesale Apple Market.

FRUIT.—AVERAGE WHOLESALE PRICES.

POTATOS.

Market remains about same as last week. Arrivals not quite so heavy. Prices about same. J. B. Thomas.

SEEDS.

LONDON: Oct. 5.—Messrs. John Shaw & Sons, Seed Merchants, of Great Maze Pond, Borough, London, S.E., write that to-day's market presented no striking or novel feature. The supply of Trifolium has come to an end. Winter Tares keep scarce; and the demand being brisk, full prices are realised. Sowing Rye continues good and cheap. The prices asked for new Clover Seeds are much above the views of buyers. In Rye-Grasses the tendency is upwards. Canary Seed is distinctly firmer; Turkish samples are realising 80s. per qr., both in Liverpool and London; the shipping demand for this article has lately much improved. For Peas and Haricots, the sale is slow; Millet, Buckwheat, and Barley keep steady.

FRUITS AND VEGETABLES.

BOROUGH: Oct. 4.—Moderate supply of green produce, and a quiet trade with steady prices. Quotations:—Cabbages, 2s. 6d. to 3s. 6d.; Marrows, 8s. 6d. to 4s. per tally; Cauli-

flowers, 1s. 6d. to 1s. 9d. per dozen; Lettuces, 6d. to 1s. per score; Carrots, 2s. 6d.; Turnips, 1s. 6d.; Parsley, 2s. per dozen bunches; English Onions, 4s. to 4s. 6d. per cwt.; Horseradish, English, 2s. 6d.; foreign do., 1s. 6d. to 2s. per bundle; English Apples, 2s. 6d. to 5s. per bushel.

SPITALFIELDS: Oct. 4.—Supplies of all kinds good; trade generally slow. Quotations:—Vegetables: Beetroot, 1s. 9d. to 2s.; Scarlet Beans, 2s. to 3s. 6d.; Spinach, 1s. 6d. to 2s. per bushel; Seakale, 10d. to 1s. per punnet; Cabbages, 3s. to 6s.; Cauliflowers, 3s. to 6s. 6d.; Vegetable Marrows, 3s. to 6s. 6d. per tally; Parsley, 1s. to 1s. 6d.; Onions, 2s. to 3s.; Carrots, 1s. 6d. to 3s.; Turnips, 2s. to 3s. per dozen bunches; frame Cucumbers, 2s. to 3s.; natural do., 9d. to 1s.; Leeks, 2s. to 3s.; Cabbage Lettuces, 3d. to 6d. per dozen; Horseradish, 1s. to 1s. 2d.; Celery, 10d. to 1s. per bundle; Spanish Onions, 5s. 3d. to 6s. per case; Dutch do., 2s. 9d. to 3s. 9d.; Belgian do., 2s. 9d. to 3s. 6d. per bag of 110 lb.; Brussels Sprouts, 1s. 6d. to 2s. 6d. per half-sieve. Fruit: English Apples, 2s. 9d. to 6s. 6d. per bushel; American do., 10s. 6d. to 18s. per barrel; English Tomatoes, 4s. to 5s. per peck; foreign do., 1s. 6d. to 2s. per box; Pears, 2s. 6d. to 5s.; Victoria Plums, 3s. 6d. to 4s. 6d.; Damsons, 3s. 6d. to 4s.; Bullaces, 2s. to 2s. 6d. per half-sieve.

STRATFORD, Oct. 4.—There has been an excellent supply of all kinds of produce at this market during the past week, and a brisk trade has been done in the undermentioned quotations:—Cabbages, 2s. 6d. to 4s. per tally; Greens, 2s. to 2s. 6d. per dozen bunches; Cauliflowers, 1s. to 1s. 6d. per dozen; do. 4s. to 5s. per tally; Turnips, 1s. 6d. to 2s. per dozen bunches; do., 30s. to 50s. per ton; Carrots, household, 35s. to 40s. per ton; do., cattle feeding, 25s. to 3s. do.; Parsnips, 2s. 6d. to 3s. per cwt.; Mangolds, 15s. to 19s. per ton; Swedes, 20s. to 27s. 6d. do.; Onions, Dutch, 4s. to 4s. 6d. per bag; do., Portuguese, 5s. 6d. to 6s. per case; Apples, English, 2s. 6d. to 5s. 6d. per bushel; do., American, 12s. to 14s. per barrel; Potatoes, Beauty of Hebron, 55s. to 65s. per ton.

FARRINGTON: Oct. 5.—Quotations:—Onions, Spanish, 5s. 6d. per case; Celery, 10s. per dozen rows; Turnips, per bag, 50s. to 60s. per ton; Cauliflowers, 6s. per tally; Cabbage, 5s. to 5s. 6d. do.; Pears, Callipast, 7s. per bushel; Apples, King Pippins, 4s. 6d. do.; good cooking, 4s. 6d. do.; Grapes, white Lisbon, 12s. per box.

POTATOS.

BOROUGH: Oct. 4.—Quotations:—English Magnum Bonum, 40s. to 60s.; Hebrons, 40s. to 60s.; Snowdrops, 50s. to 80s. per ton.

SPITALFIELDS: Oct. 4.—Quotations:—Snowdrops, 65s. to 80s.; Sutton's Abundance, 50s. to 60s.; Fillingbasket, 50s. to 60s.; Reading Wonders, 50s. to 55s.; Bruce Magnums, 50s. to 60s.; Early Rose, 50s. to 55s.; Hebron, 50s. to 70s.; Imperators, 45s. to 60s.; Magnums, 45s. to 60s.; Sutton's Early, 45s. to 60s. per ton.

STRATFORD: Oct. 4.—Quotations:—Dark land, 40s. to 50s.; light do., 50s. to 70s.; Imperators, 50s. to 65s.; Sutton's Abundance, 55s. to 65s. per ton.

GENERAL AVERAGES: Oct. 5.—Snowdrops, 60s. to 80s.; Hebrons, 50s. to 75s.; Magnums, 40s. to 60s.; Kidneys, 55s. to 65s.; Imperators, 50s. to 60s.; Early Rose, 50s. to 60s. per ton.

FARRINGTON: Oct. 5.—Quotations:—English Magnums, 60s. to 65s.; Snowdrops, 65s. to 70s. per ton.

HAY.

Averages.—The following are the averages of the prices at the principal metropolitan markets during the past week:—Clover, prime, 80s. to 112s.; do., inferior, 46s. to 75s.; Hay, best, 60s. to 107s.; do., inferior, 26s. to 50s.; and Straw, 20s. to 40s. per load.

CORN.

Averages.—Official statement of the average prices of British corn, imperial measure (bushel) for the week ending October 1, and for the corresponding period last year:—1892: Wheat, 27s. 10d.; Barley, 27s. 11d.; Oats, 18s. 0d. 1891: Wheat, 31s. 1d.; Barley, 28s. 10d.; Oats, 18s. 5d.

NOTICES TO CORRESPONDENTS.

PHOTOGRAPHS, DRAWINGS, OR SPECIMENS.—We shall be pleased to receive from our Correspondents notes relating to interesting Gardens, together with Specimens or Illustrations of interesting Plants. Although circumstances prevent us in all cases from reproducing them, we are nevertheless glad to receive them, and as far as possible to utilise them for the benefit of our readers.

BOOKS: W. T. A Manual of Injurious Insects, with Methods of Prevention and Remedy, by Miss Ormerod. Second edition. (Simpkiss, Marshall & Co.)

CORRECTION: In report of Cheltenham Show in our last issue, Mr. J. Clear was stated to have exhibited for Lord Sudeley. It should have been Mr. D. Sheppard, another of Lord Sudeley's head gardeners.

CUTTING AND ROLLING TURF READY FOR RELAYING: P. P. P. The number would vary from 100 per hour in light land, free from stones, to 40 or 50 per hour in clayey, hard soil; and with stones in it, the number would not average 30. You would want in heavy or stony land, an assistant to pull the tool whilst the other man shoves and guides it, and another to pile it ready for the carts. We do not know what the wages are that you pay for ordinary labour in your district. In 1 acre, there are 14,520 turves 1 yard long and 1 foot wide. Squares of 1 foot are much handier; they do not break much, not being rolled up, and are as soon laid down as the former. The cost of relaying turf, exclusive of carting, would be about one-half the price of cutting. But much always depends on the celerity of the workmen.

FUNGUS: W. T. The fungus you send is the dry-rot fungus, Merulius lachrymans. You must take up and burn the flooring boards, remove the soil beneath, and fill up with lime or cement. Take care there is sufficient ventilation.

MILDEW ON NECTARINES: J. D. The locality is, owing to some cause not suitable to their culture, or management of the tree, is wrong. Another season you should apply early some one of the many remedies for fungous-moulds mentioned in these pages.

MUSCAT GRAPES: W. B. The Grapes sent show that the vine are still capable of producing fine berries and bunches, but they are shanking very badly. It may be from the over-cropping, as you suggest, or from the roots having reached an unsuitable soil, or a depth where the sun's heat is little felt, or where the air cannot penetrate. Examine the roots as soon as you conveniently can, bringing them up if deep in the soil, affording them some new soil, and making sure that the drainage of the border and adjacent land is what it ought to be.

NAMES OF FRUIT: J. L. 1, King of the Pippins; 3, Dumelow's Seedling; 4, Yellow Ingestre; 5, Jefferson; 6, Hoary morning.—H. D. 1, Duchesse de d'Angoulême; 2, Benrié d'Amanlis; 4 (?), Marie Louise; 5, Easter Beurré. One Plum half rotten, and the two Crabs cannot be identified.—W. B. G. 1, Warner's King; 2, Gloria Mundi; 3, Hambleton Deux-ans; 4, Hoary morning; 5, Gravenstein; 6, Hanwell Sourcing.—W. Parkins, 1, Scarlet Nonpareil; 3, Sturmer Pippin; 4, Yorkshire Beauty; 6, Spice Apple; 8, Northern Greening, Pear Swan's Egg.—J. E. 1, King of the Pippins; 2, Red Astrachan.—J. B. Jones, Pear Brockworth Park.

NAMES OF PLANTS: F. H. Stanway, 1, Picea Morinda, 2, Aesculus flava, probably (cannot name with certainty from leaves only); 4, Tilia platyphylla var. asplenifolia; 5, Fraxinus americana; 6, Pyrus pinnatifida.—J. Q. 1, Pinus strobus; 2, P. Pinaster var.; 3, P. ponderosa; 4, P. Pinaster; 5, P. montana (pumilio); 6, Picea excelsa, common Spruce; 7, Pinus Pinaster var.; 8, P. Pinaster var.; 9, P. Pinaster var.; 10, P. Laricio var. Pallasiana; 11, P. Laricio var. austriaca; 12, P. Laricio var. austriaca; detached cone P. ponderosa.—Somerset, 1, Panicum plicatum; 2, Cyperus Meyenianus.—W. H. H. Datura Stramonium, Thorn Apple, Solanaceæ, poison.—G. O. Passiflora cœrulea, probably from the leaf (Passiflora, from South Brazil).—R. S. Euphorbia Cyparissias (Euphorbiad, native of Switzerland).—W. 1, Solidago canadensis (Composite); 2, Pyrethrum lactustræ (Composite); 3, Leycesteria formosa (Caprifoliad); 4, Antennaria margaritacea (Composite); 5, Pyrethrum uliginosum (Composite); 6, Aster novi-belgii roseus (Composite).—G. H. 1, Ailanthus glandulosa (China, Nanthoxyaceæ); 2, Pavia macrostachya (Sapindal); 3, Abies nigra (Conifer, from N.E. United States); 4, Cupressus, perhaps turulosa; cannot tell from foliage only; 5, Cotoneaster Simonsi, probably (Rosad, Nepal); 6, Rosa Banksia (China, Rosad); 7, Escallonia macrantha (Chili, Escalloniad); 8, Calycanthus occidentalis (California, from California).—T. W. R. 2, 3, 4. We believe they are all forms of Cratægus Crus-galli.—Nash, 1, Thuja filifera; 3, Fern-leaved Beech; 4, Bambusa Metake; 5, Zeltkova crenata; 6, Acer campestre; 7, Berberis vulgaris; 11, Tradescantia discolor; 12, Pteris aquilina. Without numbers Gleditschia triscanthis, Chrysanthemum coronarium.—H. G. Both varieties of Odontoglossum Lindleyanum.—J. Moore, 51, Athyrium f.-f. corymbiferum; 61, A. f.-f. cruciato-cristatum; 16, Polystichum angulare

proliferum; 21, P. a. depauperatum; 31, Lomaria (Blechnum) Spicant; 17, Polystichum acrostichoides.—P. & Sons. Ficus australis, probably, you should send a shoot, not a leaf merely.

PEACH DISEASE: *Hibernia*. What you send is what, for want of a better name, we have called silver-leaf disease. It is very destructive; but the best chance is to cut the tree hard back, and when it begins to push, give it judicious high-feeding.

PLANTS FOR A VERY DRY BORDER FULL OF IVY ROOTS: *Perplexed one*. A variety of succulents might be tried, as Sedum Ewersii, S. Sieboldii, S. spurium, Sedum acre, and the golden variety of it, S. Nevii, S. dasyphyllum, S. brevifolium, and others. Sempervivum arenarium, S. arachnoideum, S. tectorum the common species of Houseleek, and many others. These and Thymus Serpyllum, and T. lanuginosus, Vinca minor, Plumbago Larpentæ, Polygonum affine, P. complexum, might form a ground work, and in this might be planted in pots or other receptacle sunk in the ground tuberous Begonias, Begonia discolor, Balsams, Calendulas, Marygolts, Clematis, Panicum sulcatum, Aloes, Agaves, Gypsophila paniculata, Gladiolus, German Asters, Pelargoniums, Lilies, &c.

SEEDLING APPLE: *G. S.* There are many early varieties much better.

TEA, CURRANTS, &c.; *Debate*. Enquire at the Board of Trade, Whitehall.

TWIN VIOLET: *J. B. J.* Not very unusual. No doubt by patient selection you could fix the strain, but it would probably take up much time.

VIOLETS IN FRAMES IN LONDON: *Cigarette*. The plants should have been prepared from simple rooted runners, planted out in fairly good ground in April, and kept clean by hoeing, and have had all runners cut off them from time to time. If you have such plants, make up a common garden frame by making a foundation wall of dry bricks, on which to stand it; fill in the frame with coal-ash or anything hard, yet fairly close and solid, leaving space for a depth of 6 inches of light soil, consisting of loam and leaf mould in equal parts, and a space of 6 inches above that to the glass. Plant firmly about 10 inches apart, and keep the frame close for a week; afterwards giving as much air as the weather will permit, avoiding giving air when it is frosty. The frame should face due south, and have a fairly steep pitch, so as to catch every ray of sunlight. To keep out frost, make a thick lining of spent stable litter, say 1½ foot thick, and as high as the frame, and when it sinks add more. A covering of mats is required all the winter, and in hard weather some litter as well. See *Gardeners' Chronicle*, Feb. 27, 1886, p. 270.

WEIGHT OF TOMATOS IN A SPAN-ROOFED HOUSE 14 BY 50 FEET: *Tomato*. The plants might be arranged at a distance of 2 feet apart on either side, planting them in narrow trough-like border, made of boards, say 1 foot wide and 9 inches deep, and training the stems close up under the roof. That would give 50 plants, and these at 12 lb. of fruit a piece would give a total of 600 lb. weight for one set of plants—those that fruit in spring and summer. Another mode of planting would be to plant nine plants near the side at 6 feet apart, the stems to be trained as single cordons on wires, running just beneath the roof, and between this row and the centre path, plant two rows of sixteen plants in a row, that is at 3 feet from one to the other. These plants to be trained to erect stakes. This method of planting would give forty-one plants on each bed; and total produce on the two beds 41 x 2 x 10 = 820 lb., or if the eighteen roof plants gave 12 lb., the quantity would be 856 lb. It would be necessary to obtain a heavy cropping variety, such as the Old Red or a strain from it, or Carter's Orange Perfection.

MESSINGER & CO.'S New CATALOGUE of Greenhouses and Heating Apparatus,

Just issued, will be found the most complete, practical, and reliable guide to all about to build, alter, or heat Greenhouses. Illustrations of every description of Glasshouse, from the largest range of Winter Gardens to the simplest forms of Portable Greenhouses, Plant Protectors, and Garden Frames; also of all the best kind of Boilers, Hot-water Pipes, and all appliances for heating. This Catalogue, possessing hundreds of illustrations of all the latest improvements in greenhouse building and heating, is on a scale never before attempted. It should be in the hands of every one interested in gardening, as it contains many practical hints on the subjects of which it treats, the result of many years' experience. Price, 2s. post-free.

A large number of the illustrations are taken from greenhouses erected by us in various parts of the country; an inspection of this Catalogue shows, therefore, the efficiency of which has been well tested by actual use. The advantages possessed by as enable us to carry out work with the utmost promptness, and in the very best style, at prices which defy competition. Surveys made, and gentlemen waited on in any part of the country. Plans and Estimates free on application.

MESSINGER & COMPANY, LOUGHBOROUGH.

London Office:— 163, Palmerston Buildings, Old Broad Street, E.C.

THE IMPROVED GARDEN GULLY (VINCE'S PATENT).

This useful invention is a great improvement on the ordinary Garden Grating, and is especially suitable for hilly walks and drives. As they never get stopped by rubbish or sand they effectually prevent the washing away of the gravel in heavy storms, and they save half the labour in cleaning out the cesspools. The prices are:—
6-in., 1s. 6d.; 8-in., 2s.; 10-in., 3s.; 12-in., 6s. 6d.; 15-in., 8s.
(The larger sizes are very strong for carriage drives.)

Full Particulars on application. Testimonials:—

From Mr. J. WILLARD, Head Gardener to the BARONESS BURDETT-COUTIS, Holly Lodge Gardens, Highgate, N., July 12, 1892.—"Dear Sirs, Having given your Improved Garden Gully a fair trial, I may say that it proves in use all that you claim for it, and in my opinion has, for the sides of walks and drives, many advantages over the ordinary grating. Perhaps the best proof I can give you of this is that, as opportunity offers, I intend to use them instead of gratings. Faithfully yours, J. WILLARD."—To Messrs. VINCE & VINE.
From W. WALTON, Esq., Secretary to the LONDON CEMETERY COMPANY, The London Cemetery Company, 29, New Bridge Street, Blackfriars, E.C., July 25, 1892.—"To Messrs. VINCE & VINE, Highgate. I am very happy to testify that your Patent Garden Gully-Frames in lieu of the old-fashioned gratings answer admirably. They were by my authority fixed in a new pathway made in Highgate Cemetery, and in the recent thunder showers they were severely tested and were

most effectual in preventing the scouring of the gravel. At the inspection my Directors were much pleased with them, and gave instructions that they were to be used when required at Nunhead Cemetery.—I am, yours truly, W. WALTON, Secretary."

From Messrs. CUTBUSH AND SON, Highgate and Barnet Nurseries.—"Highgate Nurseries, London, July 27, 1892.—Dear Sirs,—Referring to the Improved Garden Gully you fixed for us some months ago, we are glad to say it answers admirably. As you are aware, our Nurseries here are very hilly, and during the recent storms all the ordinary gullies were blocked, whereas yours was in good working order. We shall not hesitate to recommend the same to anyone requiring the gullies for sides of paths and carriage-drives, and we feel certain, when it is known, there will be a great demand.—We are, yours faithfully, WM. CUTBUSH AND SON.—Messrs. VINCE & VINE."

WANT PLACES.

TO GARDENERS, AND OTHERS SEEKING SITUATIONS.

The Pressure upon our space at this season of the year is so great, we are compelled to state that advertisements received after 6 P.M. on Wednesday will, in all probability, be held over to the next week.

Advertisers are cautioned against having letters addressed to initials at Post-offices, as all Letters so addressed are opened by the authorities and returned to the sender.

S ANDERS, St. Albans, can thoroughly RECOMMEND several first-class HEAD GARDENERS.

Gardeners, Farm-Bailiffs, Foresters, &c.

DICKSONS, Royal Nurseries, Chester, are always in a position to RECOMMEND MEN of the highest respectability, and thoroughly practical at their business. All particulars on application.
 Telegraphic and Postal Address—"DICKSONS, CHESTER."

RICHARD SMITH AND CO. beg to announce that they are constantly receiving applications from Gardeners seeking situations, and that they will be able to supply any Lady or Gentleman with particulars, &c.—St. John's Nurseries, Worcester.

THOMAS BUTCHER can recommend several HEAD and UNDER GARDENERS of first-rate character and proved ability. Gentle-men seeking such may have particulars free.—Apply to THOMAS BUTCHER, Seed Merchant and Nurseryman, Croydon.

F. SANDER AND CO. can recommend several highly qualified and energetic HEAD and UNDER GARDENERS, of excellent character, and proved ability; men thoroughly fitted for all the various duties of their profession. For all particulars, please apply to—
 F. SANDER AND CO., St. Albans.

B. S. WILLIAMS AND SON beg to intimate that they have at present in their Nursery and upon their Register some excellent Men, competent either to fill the situation of HEAD GARDENER, BAILIFF, FOREMAN, or JOURNEYMAN. Ladies and Gentlemen requiring any of the above will please send full particulars, when the best selections for the different capacities will be made.—Victoria and Paradise Nurseries, Upper Holloway, N.

SCOTCH GARDENERS.—Several superior men of first-class ability seeking re-engagement; also UNDER-GARDENERS.—Particulars from "AUSTIN AND MCASLAN, 89, Mitchell Street, Glasgow.

GARDENER (HEAD); age 39.—JOHN HARRISON, for nine years Head Gardener to C. E. Thornycroft, Esq., Thornycroft Hall, Chelford, Cheshire, is now at liberty to engage with any Lady or Gentleman requiring the services of a thoroughly efficient and experienced man in all branches. Unexceptional character from present and past employers.—Address as above.

GARDENER (HEAD).—In the prime of life; married, no family; thoroughly experienced in all branches. Twenty-five years' excellent character as Head. Will be disengaged on November 1, and is leaving of his own accord.—HEAD GARDENER, Ulcombe Place, Staplehurst, Kent.

GARDENER (HEAD).—£10 Bonus will be given by Advertiser for information resulting in an engagement as above, where eight or ten men are kept. Thoroughly experienced in every branch, including Orchids. Age 31; highest possible character.—Particulars to R. S., Gardeners' Chronicle Office, 41, Wellington Street, Strand, W.C.

GARDENER (HEAD), where two or three are kept.—Age 39; well up in all branches. First-class reference. Fifteen years' experience.—A. B., Mrs. Cheer, Stroud Green Road, Shirley, Croydon, Surrey.

GARDENER (HEAD).—The Rev. H. EWANK is desirous of recommending a Head Gardener, who has been living for some time in his parish. He has a good knowledge of the different branches of Gardening, understands the Cultivation of Orchids, is well acquainted with Grape Growing, &c. He is, besides, a most respectable man, and, in the opinion of advertiser, likely to give great satisfaction to any employer.—Address, for any further information, Rev. H. EWANK, St. John's Vicarage, Ryde.

GARDENER (HEAD WORKING).—Age 36, married, no family; thoroughly experienced in all branches. Four and half years' good reference. Wife helps in house, if required, or attend to Poultry.—M. SEALEY, Cambria Cottage, Main Road, Sidcup, Kent.

GARDENER (HEAD WORKING).—Age 32.—married; seventeen years' experience; eight years as Foreman in last place. Thoroughly competent, energetic, and trustworthy. Good references.—HORTUS, 5, Railway Terrace, Wincheap, Canterbury.

GARDENER (HEAD WORKING).—Age 37, married; thoroughly experienced in all branches of Gardening. Excellent character from present and past employers.—GARDENER, Little Heath, Potter's Bar, Herts.

GARDENER (HEAD WORKING), where one or two more are kept.—Married, two children, one from home. Experienced Inside and Out. A GENTLEMAN highly recommends a trustworthy man as above; has been with him fourteen years; satisfactory reasons for leaving.—GARDENER, Tollerton Hall Gardens, Notts.

GARDENER (HEAD WORKING).—Age 30, married; sixteen years' practical experience in all branches of the profession. Eight years Foreman to the late Miss Cavston. Excellent testimonials.—F. EVERITT, Gosfield, Halstead, Essex.

GARDENER (HEAD WORKING).—Thoroughly experienced in Vines, Melons, Cucumbers, Tomatos, Mushrooms, &c. Stove and Greenhouse Plants, Flower and Kitchen Gardens. Good references.—E. BOOKER, 59, Kingford Road, Wandsworth, S.W.

GARDENER (HEAD WORKING), where one or two are kept.—Age 32, married if suited; abstainer. Understands Vines, Cucumbers, Melons, Tomatos, Stove and Greenhouse Plants, Flower and Kitchen Garden; life experience; eight years' good character.—JAMES JUPP, Brantridge Gardens, Balcombe, Sussex.

GARDENER (HEAD WORKING).—Married. Life experience in Vines, Peaches, Cucumbers, Melons, Tomatos, Stove and Greenhouse Plants, Flower and Kitchen Garden, &c. Eleven years' good character, nine previously.—T. T., The Limes, Coggeshall, Essex.

GARDENER (HEAD WORKING), where two or more are kept.—Age 30; life thorough practical experience in all branches. Excellent testimonials and character for over sixteen years. Three years in present situation as Second. Reference kindly permitted by present employer, E. F. Studd, Esq.—H. MORRIS, Oxtou Gardens, Exeter.

GARDENER (HEAD WORKING).—Age 34, married; thorough all-round man. Fifteen years' good practical experience in Fruits, Flowers, and Vegetables. Excellent references.—E. BIRD, Badfair, Trefnant, North Wales.

GARDENER (HEAD WORKING).—J. COMBER, Foreman, The Gardens, Drankstone Park, Bury St. Edmunds, seeks engagement with any lady or gentleman requiring a first class gardener, fourteen years experience in all branches, including Orchids. Abstainer. Excellent testimonials.

GARDENER (HEAD, or good SECOND).—Age 29; twelve years' good practical experience in all branches. Good testimonial from last situation.—A. M., 2, Rochester Cottages, Cavendish Road, St. Albans, Herts.

GARDENER (HEAD, or SINGLE-HANDED).—Age 25; understands Flower and Kitchen Gardens, Greenhouse, Vinery, Frames, and Wall Fruit.—J. B. S., Amyand Cottages, Amyand Park Road, Twickenham.

GARDENER (HEAD, or SINGLE-HANDED).—Married, two children; two years' character from present employer. Leaving through Estate being sold.—A. ALDERMAN, Gardener, Staple Hall, Bletchley, Bucks.

GARDENER (SINGLE-HANDED, or with help).—Age 27. Good reference.—F. RUSH, 21, Acton Street, Gray's Inn Road, W.C.

GARDENER (SINGLE-HANDED).—Age 27, married when suited. Understands Stove and Greenhouse Plants, Cucumbers, Tomatos, Kitchen Garden, and the general routine of Gardening. Total abstainer. Good references.—H. WAYLING, Cold Harbour, Waddon, Croydon, Surrey.

GARDENER (good SINGLE-HANDED).—State age, family, experience, wages, &c.—H. G., Stevens, New-agent, Leytonstone, E.

GARDENER (good SINGLE-HANDED, or where help is given).—Age 25; four years' good character.—H. WOOD, Little Dalby, Melton Mowbray.

GARDENER (SECOND, or SINGLE-HANDED), where help is given. Single, age 25; good experience in Glass, Flower and Kitchen Garden. Good character.—A. H., The Grange, West Heath, Hampstead, N.W.

GARDENER (SECOND).—E. SILENCE, Gardener to Earl Fitzwilliam, Eastcliff, Bamberge, Isle of Wight, wishes to recommend a young man (age 24) of excellent character as Second Inside and Out; nine years' experience, three years in present place.

GARDENER; age 30, married, one child. Mrs. FIPPINGE, through giving up her Establishment, can with confidence highly recommend her Gardener, F. FRANCIS, where three or more are kept. Experienced Inside and Out. Good references from previous employers. Please address, first instance, F. FRANCIS, Mayford House, near Woking.

GARDENER (UNDER, or SINGLE-HANDED).—Married, one child; four years' good character from last place.—F. H., 19, Burrard Road, West Hampstead, London, N.W.

GARDENER (UNDER), Inside, or Inside and Out.—Age 29. Six years' experience. Good references. Abstainer.—J. B. LOWE, Runfold, Farnham, Surrey.

GARDENER (UNDER).—Age 26. Three years' good character; four previous.—J. ALEY, 7, Manor Terrace, Clewer Green, Windsor.

PROPAGATOR and GROWER.—Age 29; life experience in Tomatos, Cucumber, plants, Ferns, Rose, Bulbs, Forcing, Wreaths, Bouquets, &c.—GROWER, 10, Sayer Street, Huntingdon.

FOREMAN, PROPAGATOR, and GROWER of Palms, Dracenas, Encharis, Ferns, Carnations, Chrysanthemums, Double Primulas, Pelargoniums, Clematis, Bonvardias, Roses, Cucumbers, Tomatos, Wreaths, &c.—W. GREEN, 190, King's Road, Kingston-on-Thames.

TO FLORISTS.—A Young Lady, thoroughly experienced, seeks re-engagement. A good hand at Wreaths, Crosses, Shower Poses, Sprays, &c. First-class references.—A. B., 119, Upper Standhope Street, Liverpool.

HOLLOWAY'S PILLS AND OINTMENT.

Hypertension, Jaundice—These complaints are the result of a disordered liver, which secretes bile in quality or quantity incapable of digesting food. Digestion requires a free flow of healthy bile, to insure which Holloway's Pills and Ointment have long been famous, for clipping any other medicine. Food, irregularity of living, climates, and other causes are constantly throwing the liver into disorder, but that important organ can, under all circumstances, soon be regulated and healthily adjusted by Holloway's Pills and Ointment, which act directly upon its vital secretion. The Ointment rubbed on the skin penetrates immediately to the liver, whose blood and nerves it rectifies. One trial is all that is needed; a cure will soon follow.

AWARDED TWENTY PRIZE MEDALS

AT INTERNATIONAL EXHIBITIONS AT HOME AND ABROAD.

KEITH'S PATENT BOILERS, THE "CHALLENGE," "VIADUCT," "PYTHON," &c.,

FOR HOT-WATER HEATING, "STAND FIRST," require no building work around them, are entirely water-jacketed, and heat from 50 feet up to 20,000 feet of 4-inch pipe respectively. Many thousands are in use all over the world, and the Boilers are unrivalled in power and economy.

Manufactured under 30 James Keith's Patents in Great Britain, United States, and Canada.

This Engraving "illustrates the most powerful form of Boiler that has yet been made for Hot-water Circulation."—Extract from HOOD, on *Warming by Hot-water*, New Edition, 1891.

KEITH'S "PYTHON" BOILER, as illustrated, has 1,000 square feet of effective heating-surface, with 17½ square feet of fire-grate area, heats about 20,000 feet of 4-inch pipe, and is the Most Powerful and Complete Sectional "Special" Hot-water Heating Boiler in the World.

JAMES KEITH (C.E., Assoc. M.Inst.C.E.), Gas, Hydraulic, Heating, Ventilating, and Consulting Engineer. Established 1823. Contractor to Her Majesty's Government. 57, HOLBORN VIADUCT, LONDON, E.C., ALSO AT EDINBURGH AND ARBROATH.

FORTHCOMING SALES BY MESSRS. PROTHEROE & MORRIS,

Horticultural Auctioneers and Valuers,

CENTRAL AUCTION ROOMS and ESTATE OFFICES, 67 and 68, CHEAPSIDE, E.C. CATALOGUES FOR ALL AUCTIONS SENT FREE BY POST ON APPLICATION.

Worcester.

FIVE DAYS' ABSOLUTE CLEARANCE SALE of about 20 Acres of beautifully-grown NURSERY STOCK, carefully prepared for removal, by order of Messrs. Richard South & Co., a portion of their land in the City boundary being required for Building purposes.

Important to Noblemen, Gentlemen, Land-cape Gardeners, Nurserymen, and others engaged in Planting.

MESSRS. PROTHEROE AND MORRIS will SELL by AUCTION, on the Premises, the St. John's Nurseries, Worcester, about 20 minutes' walk from the Worcester Railway Station, on MONDAY NEXT, October 17, and FOUR FOLLOWING DAYS, at 12 o'clock precisely each day, without reserve—

25,000 STANDARD and PYRAMID ORNAMENTAL TREES, 4 to 18 feet, in great variety; 2000 Prunus pissardi; 3200 Purple Beech, best dark-leaved variety; 500 London Planes.

5000 FLOWERING SHRUBS in great variety.

12,000 SPECIMEN CONIFERS and EVERGREENS,

1 1/2 to 12 feet high; 2000 Portugal Laurels; 1600 Gold and Silver Variegated Hollies, Standards and Pyramids; 2500 Gold n Yews, grand plants.

Large quantities of fine Native LARCH, 2 to 1 feet.

Ash, Quick, and other FOREST TREES.

Thousands of FRUIT TREES, including Standard and Pyramid Pears, hundreds of Standard Victoria Plums, grand trees; Standard and Pyramid Damsons, Standard and Pyramid Apples, Black and Red Currants, Whinham's Industry, Keepsake, and other popular gooseberries.

Several hundreds of fine Planting and Fruiting VINES.

Forcing ASPARAGUS

Thousands of TEA and NOISETTE ROSES, in pots, embracing the most popular plants.

Thousands of CLIMBERS, consisting of 10-0 Clematis Jackmanni, 100 Clematis in variety.

Berried ACCUBAS, in quantity, and other Stock.

Also 8 two-wheel TRUCKS, and 1 smaller do., suitable for Nurserymen and others.

The Auctioneers desire to call special attention to this highly important Sale. It is the first occasion on which an Auction has been held at these celebrated Nurseries, the necessity now arising solely on account of a portion of the ground having to be given up for building purposes; and the present Sale affords an exceptional opportunity to Noblemen, Gentlemen, and others desirous of acquiring large quantities of well-grown Nursery Stock.

Purchasers may arrange with Messrs. Smith & Co. to have their lots lifted and forwarded at the cost of labour incurred and material used. Lifting provided each day at 11.30.

The Stock may be viewed any day prior to the Sale. Catalogues may be had on the Premises, and of the Auctioneers, Estate Agents, and Valuers, 67 and 68, Cheapside, London, E.C.

VICTOR POTATOS

(SHARPE'S).

This favourite first early Potato, suitable for any Garden, indispensable for Forcing and Early Borders, and likely to take the first rank amongst first earlies for market use. Quality and yield all that could be desired. One well-known market grower has this year had a yield of 15 tons per acre on a large acreage. London and Manchester salesmen speak highly of their quality, and report that Victors will keep their bloom and have a fresh appearance after being in the market some days, when other early Potatoes have become discoloured and unsaleable.

The stock we offer is the true yellow-fleshed variety and not the white variety, which is often substituted.

Price per cwt. and ton. State requirements to

THE Gardeners' Chronicle.

SATURDAY, OCTOBER 15, 1892.

TENNYSON AS A NATURALIST.

THE whole nation is lamenting the loss of its sweetest singer, and of the poet who, most of all, was in touch with the spirit of his time.

Those now in middle life are recalling the days when their hearts beat high and their pulses throbbed as they were uplifted by the noble trumpet-call of *Locksley Hall*, or hastened by the exquisite melody of *In Memoriam*. Whether joyfully acclaiming the signs of progress and of widening thoughts, or reverently looking forward to the unknown future, Tennyson was the idol of those treading with wonder, exultation, but withal with veneration, the paths of science in the middle of the century.

Science indeed has found no more appreciative sympathiser among the poets than it has in Tennyson. His poems teem with allusions which none but a naturalist would make. They are imbued with all that is good and beautiful, and true and hopeful in science. They manifest intelligent sympathy with its wondrous conquests, and its noblest aspirations—

"With the fairy tales of Science and the long result of Time."

Mark these pre-Darwinian illustrations of the principle of evolution?

"Yet, I doubt not through the ages one increasing purpose runs,
And the thoughts of men are widened with the process of the suns."

"Whose faith has centre every where,
Nor cares to fix itself to form."

"One God, one law, one element,
And one far-off divine event,
To which the whole creation moves."

And is not this a reflex of the teaching of Owen and of Huxley?

"So careful of the type, she seems
So careless of the single life."

These and a hundred other illustrations show how closely the great poet was in touch with the science of the day.

The very method he employed in his literary work, his striving after accuracy of detail and perfection of statement, the care with which he polished his exquisite melodies, are they not also indications of the scientific tendencies of his mind?

The hero-worshippers were afterwards, it is true, led to wonder at the incongruity of seeing Tennyson, "Alfred Tennyson," a lord! A peerage could confer no possible dignity on him, nor, as it proved, did he lend strength to the august assembly of which he became a member.

Williams

- GARDENIAS, best sorts, well budded.
- LILAC ALBA VIRGINALIS, fine pot plants from Paris.
- " CHARLES X. " " "
- " PERSICA. " " "
- LILIUM HARRISI, extra strong, from America.
- PRIMULA SINENSIS ALBA PLENA, in fine varieties.
- ROSES, finest Teas and Hybrid Perpetuals, strong plants grown in pots for forcing.
- SOLANUM HYBRIDUM, Empress, and other kinds.

GRAPE VINES. Orders are now being executed for Vines. The canes are very fine this year and well-ripened.

For Complete List and Prices, see Illustrated Bulb Catalogue, Gratis and post free on application.

B. S. WILLIAMS & SON

Victoria and Paradise Nurseries,
UPPER HOLLOWAY, LONDON, N.

Worse still, the devotees have had to wince at the depressing contrast between the original *Locksley Hall* and its sequel, *Sixty Years After*. It may be that the lesson is as true and as useful in its way as was the outpour of faith and hope in earlier times, and that the story would have been incomplete and less true to Nature if the despondency of the octogenarian had not been depicted for us, as well as the buoyant hopefulness of the youth; but for all that, it is a disheartening shock to faith. Was this the man who once could say—

"Oh, yet we trust that, somehow, good will be the final goal of ill."

A poet-naturalist, Tennyson could not fail to sympathise alike with the botanist and the gardener. Was it not he that sang of—

"The grand old gardener and his wife,"

And did he not wax eloquent over the charms of "the gardener's daughter"?

We know the sort of garden he liked—he has told of his—

"careless-ordered garden."

Some of us have been able to recognise that the phrase—

"A spacious garden full of flowering weeds," was a not inapt description of his own garden—

"Close to the ridge of a noble down."

It is clear that he had sympathies with—

"High-walled gardens green and old,"

and those wherein—

"The rusted nails fell from the knots
That held the Peach to the garden wall."

But although he sometimes looked upon ill-ordered gardens with the eye of an artist and a poet, rather than with that of a gardener, it was not always so; a casual glance through his pages shows that he was by no means insensible to the charms of a more carefully-tended garden. Here is a garden picture most of us have seen often enough—

"The garden stretches southward, in the midst
A Cedar spread his dark green layers of shade,
The garden-glasses shone, and momentarily
The twinkling Laurel leaves scattered silver lights."

And here is a sketch of the writer as he betakes himself to the home probably of the gardener's daughter—

"And cross'd the garden to the gardener's lodge,
With all its casements bedded and its walls
And chimneys muffled in the leafy Vine."

We can see the poet in imagination striding across—

"A garden-bowered close
With plaited alleys of the trailing Rose
Long alleys falling down to twilight grots,
Or opening upon level plots
Of crowned-Lilies standing near
Purple-spiked Lavender."

If by crowned Lilies the poet meant the "Crown Imperial," he was for once at fault, for the purple-spiked Lavender would hardly be in bloom at the same time.

Here are pictures of autumn in the garden just prior to the time when his—

"whole soul grieves
At the moist rich smell of the rotting leaves."

"Heavily hangs the broad Sunflower
Over its grave in the earth so chilly;
Heavily hangs the Hollyhock,
Heavily hangs the Tiger Lily."

The stately Hollyhock seems to have been a favourite with Tennyson, for he mentions it again and again. The Woodbine, the Jasmine, the Violet (a special favourite), the Acacia (Robi-

nia), Pimpernel, Rose, Lily, Passionflower, and Larkspur, all find mention in *Maud*: and throughout his poems, though we cannot stay to verify our impression, there are evidences of a fondness for flowers that are blue. But if we were to quote all the plants, cultivated or wild, that are alluded to in his poems, we should require not one, but a long series of articles. We can only mention his fondness for the river-banks and marshes—attributable, probably, to his Lincolnshire birth and Cambridge residence. Here are some pictures, the like of which must surely exist in numbers by the Cam—

"The hump-backed Willow half stands up
And bristles; half has fallen and made a bridge."

"A league of grass wash'd by a slow broad stream
That stirr'd with languid pulses of the oar,
Waves all its Lilies."

"The Oat-grass and the Sword-grass and the Bulrush in the pool."

He frequently employs the term "marsh" in speaking of the vegetation, and is full of allusions to such scenes as are afforded by "dank Willows," Poplars, Aspens, and other trees hard by—

"The sleepy pool above the dam."

The Elm, the Ash, the Oak, and the Lime, all find mention in his pages; the last tree especially was a favourite, and is more than once mentioned in connection with bees—

"The Lime, a summer home of murmurous wing."

Further illustrations might be given by the score to show how keen a sympathy Tennyson had with Nature, what a close observer he was, and what profound, yet simple, lessons he could draw from the sights and the sounds of the everyday objects that met his gaze. Enough, if we send the reader to his bookshelf, to enjoy once again the delicious melody of the Laureate's rhythm, and to be uplifted into a clearer, purer atmosphere than that which surrounds our daily tasks.

NEW OR NOTEWORTHY PLANTS.

CYPRIPEDIUM EDITILE, n. hybr.*

This lovely new hybrid has been obtained by fertilizing *Sel. conchiferum*, Rehb. f., with the pollen of *S. Schlimii albiflorum*. As *S. conchiferum* is the hybrid between *S. caricinum* × *S. Roezlii*, we have to deal with the characters of three very different species. The influence of the pollen parent being here, as usual, the prevailing one, the plant is in the way of the hybrids of the *Sedeni* group. Of the female parentage there have only remained the twisted petals and the compression of the lip, which in size and dimensions are about midway between the lips of *S. caricinum* and *S. Sedeni*, with the colour of a pallid variety of the latter. The foliage is about the same as in *S. Sedeni*. The plant was raised by Messrs. Sander & Co., and is dedicated to Mrs. Editha Boyle, the wife of the well-known literary orchidologist, Mr. J. Boyle. *Dr. Kränzlin*.

COLCHICUM DECAISNEL†

Mr. Gambleton obligingly forwards us flowers of a *Colchicum* reputed to be of this species. They are relatively small, of a very delicate shade of lilac, without any tessellate markings. The oblong elliptic

* *Cypripedium Edithae*, n. hybr.—Sepalo dorsali ovato oblongo acuto, sepalo inferiore oblongo obtuso excavato, petalis linearibus acuminatis bis v. ter tortis, labello aequilongis pilosis, labello profunde saccato subcompresso carinato margine praesertim basi profunde involuto. Stamina duo quinqueangulo postice sinuato longo piloso. Totus flos pallide roseus venis intensioribus striolatus, 2/3 pollicis diametro, labellum 1 pollicis et 3 lin. longum, 9–10 lin. profund., vix 6 lin. latum; rostrum margine albidum roseo-punctulatum, gynostemium album. Folia linearia carinata laeta viridia.

† *Colchicum Decaisnei*, Boissier, *Flor. Orient.*, v., p. 167.

segments measure about 2 inches in length, by 7 to 10 inches in width. The base of each segment is marked internally by a narrow central groove, which serves to detain the pollen-grains, so that when an insect enters the flower in search of nectar or of pollen, he must necessarily get his coat dusted with the pollen, and convey some of it to the next flower visited. The stamens are of unequal length, and the filaments have at their base an orange patch. The three styles are slightly falcate at the ends, and bear at their extremities an ovate-pointed stigma. These characters do not wholly tally with those of *C. Decaisnei* as described by Boissier; neither are the segments internally hairy, nor the anthers winged. Possibly it may be *C. latum*, with which species the one now known as *C. Decaisnei* was confused. These plants require to be studied in the living state, and, like most of the Monocots, they vary in cultivation.

IRIS NEPALENSIS VAR. LETHA.

IN the early spring of 1891, Mr. P. Barr received from Lieut.-Col. Stone a few rhizomes of "a fragrant dwarf Iris, gathered at an altitude of about 7000 feet near Fort White in Upper Burmah, on a spur of the Northern Chin Hills, called the Letha Range." These Mr. Barr kindly passed on to me; they have flowered this summer, and have proved to belong to an Iris, which from a garden point of view is very distinct and new, though for reasons which I will shortly give, I am led, from a botanical point of view, to regard it as being only a variety of the species, *I. nepalensis* of Don.

The Iris *nepalensis* of Don (*Profl. Fl. Nepal.*, p. 54), the *I. decora* of Wallich (*Pl. Asiat. Rar.*, i., p. 77, t. 86) (not to be confounded with the *I. nepalensis* of Wallich, figured under that name in *Bot. Reg.*, t. 818, for this is only an Eastern variety of *I. germanica*) is easily recognised by the peculiarities of the rhizome. This, in the resting-stage, consists of a small bud, sheathed, and completely covered up by the fibrous remains of the old leaves, from the base of which proceed a number of thick, fleshy, thong-like roots, so that it much resembles the root of *Hemerocallis*, or of an *Asphodel*. The flower, which is very fugitive, lasting for less than a day, is distinguished by the horizontally disposed, or even drooping but large inner segments, or "standards," by the large expanded crest of the style, and by the outer segment or fall bearing a conspicuous crest, cut up into a fringe, so as almost to form a beard. In a vigorous plant, the stem, a foot or more in height, bears, besides a terminal bud of two or three flowers, one, or even more, lateral flowers. The prevailing colour of the flower, a lavender, due largely to pale violet veins on a creamy ground, together with the gracefulness of its form, produce a very charming effect, and make one regret that the life of the bloom is so brief. The flowers appear very soon after the leaves begin to shoot, and the growth of the foliage is chiefly after flowering. In addition to Wallich's large plate (under the title *I. decora*), there is a very good figure in Sweet, *Brit. Flower Garden*, 2nd series, t. II. It is with me one of the latest Irises to flower, rarely appearing until July is well on.

The plant from the Letha Range exactly resembles *I. nepalensis* as far as the rhizome is concerned. I do not think that I could distinguish the two, except that perhaps the fleshy roots of the Letha plant are more cylindrical, less spindle-shaped, than those of the other. The foliage, too, is almost identical, though the leaves of the Letha plant are rather shorter, broader, and of a darker green. Nor can I see any essential difference in the form, or even in the colour of the flower, though, perhaps, those of the Letha plant are more variable as to the depth of the colour, the dilution of the violet, and, on the whole, are of a deeper colour. I have, so far, observed very little variation in the colour of *I. nepalensis*, though I have raised many seedlings. The spathe-valves of the Letha plant are more distinctly navicular, and keeled; the ripe capsule (in both cases trigonal, with deeply-grooved sides) is shorter and broader, and the seed (which in both cases has a striking appearance, due to a large white strophiole) has a blunter, less pointed end; these are the only real differences which I have observed in the flower itself.

But the two plants have wholly distinct garden effects; for while, as I have mentioned, the flower in

I. nepalensis is borne on a stem of considerable length, in the Letha plant the flower is quite sessile, nestling among the bases of the young leaves. Moreover, while the former flowers with difficulty, and scantily, at last so far as my experience goes, the latter flowers very freely, five or six flowers being borne in succession by each tuft of leaves. Further, while the former (so my experience teaches me) imperiously demands special treatment, namely, to be ripened in late autumn by being covered with lights, or "lifted" during winter, and in the absence of such treatment, soon disappears, the Letha plant is much more amenable; a plant of it left exposed, save for a little mulching, all last winter, which was rather severe, bloomed freely this summer in late June. Lastly, while the odour of *I. nepalensis* is uncertain, the Letha plant is distinctly fragrant. In a word, while *I. nepalensis* as a garden plant is worthless for general cultivation, the Letha plant seems to promise to become popular as soon as a stock of it is obtained and it becomes known. A mass of it would, at flowering time, be most charming.

One cannot, however, or one ought not to, found a new species on the simple fact of the flower being sessile; and the differences mentioned above as to the capsule and seed are too recumbent to serve as the basis for a new species. Hence, different as a gardener must consider the type and this new plant, I do not think that I ought to give the latter more than varietal dignity.

Considering how few British soldiers care to avail themselves of the botanical opportunities afforded to them in the course of their duties, how most of those sent into new unexplored regions scorn to gather the flowers, much less to collect the seeds, bulbs or roots, which we gardeners at home are longing to possess, knowing of them only by inference, I should have liked to have shown appreciation of Lt.-Col. Stone's zeal by associating his name with his plant. It would be a little set-off against the numerous Korolkowianas, Kolpakowskianas, Ostrokowskianas, and the like, by means of which we know that we owe bright spots in our garden to the good offices of Russian soldiers. But the advantages of a plant's name telling us as much about it as possible, where, for instance, it grows, has had the greater weight with me. I therefore propose to call it *I. nepalensis* var. *Letha*.

In a letter to Mr. Barr, Lt.-Col. Stone says of it: "It occurs at an altitude of about 7400 feet, and is not found below 6500, coming into bloom at the end of April" (at Shelford it flowered at the end of June). "It is not particular as to soil, so long as that is light. Where it grows there is a sharp frost at night from December to the end of February. There is usually no rain from the end of October to the beginning of March, from which time to June there are occasional showers, then S.W. monsoons and continuous rain to the end of October." This gives the lead for treatment. Keep the plants as dry as possible all through the turbulent uncertain English winter. Never let it lack for moisture from the time it begins to shoot until the foliage begins to ripen in September. *M. Foster, Shelford, September, 1892.*

ORCHID NOTES AND GLEANINGS.

DENDROBIUM PHALANOPSIS SCHRODERIANUM.

MR. JAS. CYPHER, of Queen's Road Nursery, Cheltenham, like all others who have it, speaks in the highest terms of the beauty and free habit of this fine Orchid, and sends two made-up sprays of a dozen flowers each to show how the different shades may be worked in for florists' purposes; the combinations arranged with Maidenhair Fern are very beautiful. Other examples of finely-flowered Orchids from this good cultivator are *Oncidium hæmatochilum*, *Zygopetalum rostratum*, *Z. maxillare Gautierii*, *Epidendrum xanthinum*, *Cattleya maxima*, *Oncidium cucullatum*, and *Cattleya Loddigesii*. A.

This fine introduction of Messrs. F. Sander & Co. is pronounced on all hands to be one of the most

satisfactory of recent times. It is free to grow, profuse in flowering, and the variation in the different specimens is so great that while all are beautiful, there are scarcely two exactly alike. When the plants were sold at Messrs. Protheroe & Morris' Rooms, the vendors exhibited a picture showing the great variation, and also one spike (taken from an imported dried specimen) showing thirty-two flowers; and to this most growers took exception. But already have the cultivated specimens marched closely up to the number of the drawing. Recently, the Rev. E. Handley exhibited a plant with twenty-three flowers on a spike, and now Mr. Jaques has one with twenty-six in the collection of Baron Ferdinand de Rothschild at Waddesdon.

ORCHIDS, &C., AT THE EXHIBITION OF ST. GILLES, BRUSSELS.

M. A. A. Peeters showed, at a highly successful local exhibition, a fine collection of Orchids, the season for which has been unusually favourable. We noticed among the lot several beautiful specimens of *Miltonia spectabilis* Moreliana, well-flowered; *Dendrobium formosum giganteum*, some fine *Cypripedium Wallaerti*, *Cattleya bicolor*, and *C. b. Measuresiana*; a good example of *Miltonia Rozli*, the rare *Odontoglossum Schroderi*, with its peculiar flowers which have the scent of a Stanhopea; the no less rare and beautiful *Cypripedium Chamberlainianum*, several *C. euanthum superbum*, five *Cattleya labiata autumnalis*, of different shades, but all beautiful; *Dendrobium Phalanopsis Schroderi*, *Oncidium Papilio Kramerii*, a well-marked *Odontoglossum crispum guttatum*, *Cattleya velutina*, *Dendrobium densiflorum*, *Vanda Kimballiana*, some fine *Cattleya aurea*, and an excellent *Laelia elegans Schilleriana*. M. Peeters also showed a specimen, unique in Belgium, of *Zamia tonkioensis*, with no fewer than fourteen fine leaves; and, at the same time, an excellent plant of *Macrozamia Dennisoni*; a species of *Sabal*, showing analogies with *S. Blackburniana*, and *S. Adanson*, with a stem much resembling that of *Pritchardia filifera* attracted much attention. Its great leaves presented a remarkable appearance, being transversely cut and distinctively undulated; from all the divisions hung long thin filaments. This fine Palm was also from M. Peeters.

M. A. VAN IMSHOOT'S ORCHIDS.

We noticed lately the following rare specimens in this collection:—1. *Ada Lehmanni*, with a white lip, and a central line of orange; it blooms in autumn, not in spring, as does *A. aurantiaca*. 2. *Epidendrum nocturnum*, rather rare, a native of Surinam, the stems put forth flowers in various places, the flowers resemble those of *E. falcatum*; the leaves are large, curled round a little at the base. 3. *Eulophia pulchra*, rare, lip bilobed, the lobes pointed, divided by a yellow band; the background white, with reddish-purple spots. *C. de B.*

BOTANY AND PLANT-CULTURE.

[The following extracts are taken from an address by Professor W. J. Beal at the laying of the cornerstone of the new botanical laboratory of the University of Michigan, June 24, 1892.]

Planted on yonder knoll by the wisdom of the State Board of Agriculture, between the laboratories of agriculture and horticulture, this second and better botanical laboratory is to stand. It was doubtless so located with the notion that botany is the right hand support of one and the left hand support of the other; or perhaps with a notion that botany is of a greater importance, and that agriculture and horticulture are her foremost allies.

In 1859, a third of a century ago, when I took my first degree at the University of Michigan, there was but one institution of learning in the United States that employed and paid a man for devoting all of his time to the science of botany. The person referred to was the late Dr. Asa Gray, who was for many years the Professor of Botany at Harvard University.

For the rapid and wide-spread interest and attention which botany has attracted in this country

within the past fifteen or twenty years, nothing in my opinion has done so much as the work performed in our colleges of agriculture, and in the United States Department of Agriculture.

In these days a well-equipped agricultural college cannot get along, so far as botany is concerned, by employing a man to teach botany who shall also be required to teach other subjects.

LABORATORY AND HERBARIUM.

Under good management a botanical department will advance just in proportion to the means at its disposal. This may be a suitable time for a little indulgence in considering an ideal plan for a botanical department of a college with as good an endowment and as great pretensions as this one. To attract students and give them good opportunities, the department should be many-sided and symmetrical. One or more of the teachers should be enthusiastic in field work—a good collector and well skilled in preparing plants for the herbarium. Very much yet remains to be done in systematic botany, as studied by those of the "old school," with all the aids that have come from histology and physiology, and embryology. The latter are indispensable in any course of botany. In an agricultural college, especial attention should be given to the study of grasses and other forage plants, to trees, shrubs and weeds.

Another broad and fertile field is the study of variation and description of our cultivated plants, subjects which have been receiving little attention from naturalists. There are many sections of cryptogamic botany of great interest and importance; among the most prominent of which in an agricultural course are the study of parasitic fungi and bacteria. For several years we have added annually 5000 or more plants to our herbarium. This should include specimens of cultivated plants, such as grown in the vegetable gardens, orchards, and those which are grown for flowers or foliage.

Such a college must have a good supply of compound microscopes, so that only one person shall have access to the same instrument during any term. New and improved instruments are all the time appearing, and we must have them or suffer the consequence of falling behind the times.

Microtomes, a host of re-agents, apparatus for experiments in plant physiology, maps, charts purchased or made to order, must be all the time accumulating, even though the garret become replete with old rubbish. Lantern views and means to use them, and conveniences for photographing objects large or microscopic are indispensable in 1892.

For I have been experimenting and watching the effects of numerous lectures given to students on botanical subjects. I have kept reducing the lectures, and instead have given the students references to first-class books, in which they could in connection with original work, read and take notes to better advantage than when following a lecture. Our botanical books are far better and more numerous than they used to be. As nearly all of you know, for some time past, we have kept on the shelves or on the tables of the botanical class-rooms, from five to ten or more copies of such books as, *Sach's Text-Book and Lectures on Physiology*; *De Bary's Comparative Anatomy of Phanerogams and Ferns*, his *Morphology and Biology of the Fungi, Mycetozoa and Bacteria*; *Goebel's Outlines of Classification and Special Morphology of Plants*; *Strasburger's Handbook of Practical Botany*; *Bersey's Botany for High Schools and Colleges*; *Powright's Monograph of the British Uredinæ and Ustilaginæ*; *Gurill's Uredinæ, Erysiphæ and Bacteria*; *Bower's Course of Practical Instruction in Botany*; *Campbell's Elements of Structural and Systematic Botany*; *Cryptogamic Botany* by Bennett and Murray; numerous bulletins of the U. S. Dept. of Agriculture, especially those of the section of vegetable physiology; *Goodale's Physiological Botany*; *Gray's Text-Book*, and *Plant Dissection* by Arthur Barnes and Coulter. The plan of freely using these books as needed in place of numerous lectures works admirably. A good library is one of the requisites of our ideal Botanical Department.

Our thrifty Botanical Club of thirty members, meeting voluntarily three or four times a month, demands some hints and some time at the hands of the teachers in this department.

BOTANIC GARDEN.

Greenhouses in variety we have already. Some day we should have one for use in summer in which to grow plants of cold regions. In these houses, to serve botany best, should be placed a greater variety of plants to illustrate certain points of culture, or

plants of economic importance. We have a botanical garden, recently much enlarged, but still with room enough for far greater extension. In such a garden there are, or will be, sunny slopes and shady banks, ponds and bogs, and an arboretum for specimen trees and shrubs.

Here we have, perhaps, 200 acres, which contain our buildings, the orchards, gardens, lawns, groves, and playgrounds, saying nothing about experiment plots and the fields to the south of us. Let us imagine the valley along our Iszy brook filled to the top of its banks on either side with hardy herbs and shrubs, with extensions in suitable places along the flats of the Red Cedar, and on the north bank of this quiet stream, from the boiler-house to the west entrance at the foot of the hill, a distance of nearly three-quarters of a mile. The plants in question should be to a great extent grouped by families and genera, each plant occupying a much larger space than is customary in any botanical garden which I have ever seen or read about. For example a patch of *Viola pedata* should be well grown, and not less than 3 feet in diameter; of *Helianthus orgyalis*, 6 to 10 feet; *Peltandra undulata*, 8 feet or more. So of sedges and grasses, which have not been introduced for use in masses, as they might well be. In numerous cases, whether we wish it or not, it is better to grow plants much alike each other a little way apart, with something else between them, especially where they are inclined to mix by seeds or root-stalks.

Again, I have learned by experience, that in very many cases it is easier to shift plants to other places every few years than to take up and change the soil and reset in the same spots. A rotation of crops is a good practice for a botanical garden, as well as for fields of grass and grain for the farm, or berries and vegetables for the garden. This occasional shifting of plants may seem to some too unstable for a well-planned botanical garden. On the campus, in connection with our large groves and groups of trees and shrubs, could be planted one or more good specimens to represent many families or genera of hardy woody plants. The scattering of duplicate trees, shrubs, or herbs is unnecessary, and tends to confusion in a botanical garden, but it may often be just the thing to produce the best effect for ornamenting a campus, a park, or a cemetery. For such a garden, we should need a map, lists of plants in alphabetical order, and everything well labelled.

With a course of instruction like ours, extending through the summer months, a botanical garden is of much greater value if possible than it can be to a college which takes a long summer vacation. Such a garden, with all the accompaniments to which I have referred, could not fail to make itself felt in advancing agriculture and horticulture as well as botany. This campus would more than ever interest visitors from all parts of the State, but would be of great value to the neighbouring city, and serve the place of one of its parks. In more than one of my former reports I have dwelt at length on the relations of botany to agriculture, and attempted to show the great value of botany as a study to cultivate the observation and strengthen the reasoning powers.

We have already made a good beginning towards such a garden in the broadest sense; including species and varieties in the experiment station, we now have not far from 5000. To maintain an establishment in a creditable manner money is needed, I will not say how much, but considerable, the more the better.

This college is supported mainly by the United States government, and to a considerable extent also by the State. Perhaps this condition of things may tend to prevent endowments by wealthy persons. The endowment of a botanical garden is comparatively a new way of spending a fortune in this country, and perhaps in any other country. The only instance that has come to my knowledge of a person liberally endowing a botanic garden is that of the late Hon. Henry Shaw, of St. Louis, Mo.

The chief use of a botanical department here is to give instruction to students, especially the sort of botany of greatest value to the farmer.

RESEARCH.

Another object should not be lost sight of, viz., original research. If the teacher's time, and that of his assistants, is fully occupied with routine work, nothing can be done by way of investigations. A college will fail in a very important part of its work, if no provision is made for research by its teachers. This gives them a chance to grow, inspires them with enthusiasm, and is a great help to the students, and to the world at large.

On this subject, Dr. Farlow, one of Harvard's brightest men, says, "What does investigation mean?"

It does not mean anything which is of necessity capable of partial application at first sight. The investigator is a dull, plodding mortal, working away year by year. But, at last, he discovers something which is of benefit to all mankind. You should not hurry the investigator—we must have a report in six months; we must have a report in a year; tell us about this thing, about that thing, or about the other thing. An investigator is one who knows what he is about, and he knows a great deal better than you do. He is one who has been trained, who has studied deeply, who is thoroughly in earnest."

Dr. Trelease, the director of the Shaw Gardens, says, "No one who has not himself done original work can appreciate the slowness with which results are obtained." I have often heard similar remarks from Dr. Gray, one of the most industrious and successful of investigators of the present century.

To summarise: I note the rapid progress which botany has made in this country, attributing the increased number of workers largely to the agricultural colleges and the United States Department of Agriculture. At present, botany is recognised in all of our best colleges as an important part of instruction, for the knowledge, culture, and discipline it affords. In these institutions investigations in great variety are carried on in all families of plants, from the highest to the lowest. For the best results a botanical department must be many-sided, with teachers who are experts in numerous directions. We must have a well-kept and continually-growing herbarium. Such a department should have as many compound microscopes as there are students using them in any term, and much other apparatus for experiments and photography. Duplicate volumes of books are needed, besides a generous library. A botanical club or society, which shall meet as does the one here, every week. The department will not be complete without a museum of plant products. There must be numerous greenhouses, varying in temperature and light and moisture; also a botanic garden and arboretum. Original research must not be neglected nor crowded out, nor should the study of varieties of cultivated plants.

A liberal and uniformly increasing and permanent endowment is indispensable. In addition to what the nation and the state are likely to afford for this purpose, we seek a cultured gentleman or lady of wealth, who shall interest himself in a most substantial manner. In aiding such work follows a guarantee that the name of such person shall be kept green, bear frequent blossoms, and a liberal harvest of fine fruit for centuries to come.

UNITED STATES.

THE COLUMBIAN EXPOSITION.—A highly-interesting consignment of plants was recently received from the Australian Government, comprising Tree Ferns, Stag's-horn, and Filmy Ferns, the majority of them arriving in excellent condition. The specimens of *Platycerium alaicorse* are very fine; they are established on the trunks of trees, and being admirably packed, they bore the journey well. Twelve specimen plants of *Macrozamia spiralis* accompany this exhibit, and three plants of *M. Denisoni*. Among the Tree Ferns, there is an interesting twin, consisting of two large plants, *Alsophila australis* and *Dicksonia antarctica*; these two plants are joined closely together for about 3 feet up above the roots. It is Mr. Thorpe's intention to make a display of Filmy Ferns in the grotto composing the interior of the artificial mound, now being erected under the main dome of the horticultural building. This building certainly occupies the most charming site on the grounds, with the lagoon and island in front. It is a vast structure, dwarfing, by comparison, the Horticultural Hall at the Centennial Exposition.

At present preparations are being made for the dedicatory ceremonies in October. Owing to the immense space to be adorned, the decoration must consist of showy plants in masses. Early Chrysanthemums will be used, huge plants of the African Marigolds, planted in boxes; *Salvias*, *Cosmos*, and *Coleus*, in addition to the Palms and other decorative plants. Some of the Pansy beds in front of the building are now being planted; they will be protected during the winter by frames. Some 80,000 plants are now put out in temporary beds at the back of the building. These plants will all be wintered in cold frames.

The heating apparatus, now being arranged in the Horticultural Building, is new to us here, though Mr. Thorpe says it was tried at Chatsworth years ago. It is the Polmaise system of hot air, and, with new and improved apparatus, is said to be thoroughly efficient.

The *Calceolaria* display will be looked for with much interest, especially by those who have seen it as it is grown in Great Britain. It is a very difficult plant for American growers, suffering severely from our hot summers. At the Exposition grounds, Mr. Thorpe has the young plants plunged on a bench having a false bottom, in which ice is stored; this gives the cool-bottom temperature needed, which cannot otherwise be secured. *Calceolaria* seed has been provided by many prominent European firms, and it is all being grown under precisely the same circumstances, giving a fair test to the different strains. *Primulas* are being grown in the same way, and we expect to see a superb display during the winter. A quantity of Cacti and Agaves, including a picturesque lot of *A. aloifolia* from Florida, will be utilised in forming an Arizona garden next year; fine decorative specimen plants are being frequently received from private collections in America, and we are promised a large display from Canada.

The West Indies furnish an interesting display of economic plants, already received; it includes Sugar-cane, Annatto, Coffee, Cocoa-nut, and other plants of commercial value. The Californians promise a special display of Pampas-grass, which forms an important industry in that State. *E. L. Taplin, Chicago, U.S.A.*

DAMPING-OFF OF THE BLOOMS OF CHRYSANTHEMUMS.

Now that the blossoms are fast developing, complaints of damping will soon reach us from growers of exhibition blooms. This is an evil which the cultivator has to contend with, and than which nothing is more troublesome in the whole range of Chrysanthemum growing, and many hours of anxiety would be spared us if damping-off were unknown. I have not yet met anyone who grew ever so few plants on the large-bloom principle, but had experienced loss of bloom from damp.

Opinions differ very much as to the cause, but I will explain how it affects the flowers and its cause, and show the best method of checking it. It will perhaps be best to state, at first, how the flowers are affected, for the information of those who may have had no experience of it, owing to their not cultivating plants for large blooms for exhibition, or for home decoration. There are two sorts of damping, one which affects the entire flower in its earliest stage of development, and the other which causes its more gradual decay. The former is often caused by a sudden burst of sunshine coming after a period of dull weather, which has made the petals soft, immature, and have only just commenced to unfold. I have seen partly-expanded blooms go off entirely on the morning following a bright day, just as though they had been parboiled. The most annoying form of damping is the following: Take for instance a large, three-parts expanded bloom of *Empress of India*—the florets appear quite solid, and the prospect of securing a handsome bloom very probable; but a close examination will disclose several brown specks, which a cursory glance would overlook, that resemble dust in appearance. In a short time—the next day, perhaps—the dust-like specks will be found to have increased considerably, quite half the florets being attacked; and after the lapse of a few days the disorder will have spread so rapidly that large holes can be seen in them, and if this continue a few days longer the flower is spoiled entirely. It attacks the Japanese varieties in exactly the same way. If a floret in the first stage of damping were placed under a strong lens, a tiny blister-like bubble pushing up under the surface of the petal would be observed, and if the epidermis is broken carefully, a liquid would run from the wound. I have pointed out the manner in which the blooms

are affected by damping; I will now explain my views respecting the cause.

I am decidedly of the opinion that the main cause lies at the roots. I have repeatedly proved that those plants on which the flowers damp are not in a healthy state at the roots. It may not always be that defective root action is caused by excess of stimulants applied to the roots, but in the majority of instances it is so. The plants are gorged with artificial stimulants to make them as gross and thick as possible, to produce the extremely large blooms there is such a hankering after nowadays, that the

heard of was in a place whence show blooms went to exhibitions. Here the Japanese varieties were in the charge of one man, while another attended to the incurved. The former, thinking to outdo his rival, incautiously applied a too-strong dose of chemical manure, which the plants would have been better without, as it caused a serious check. The blister-like spots on the petals previously alluded to go a long way to prove that damping is, in the main, a constitutional disorder. Who ever heard of blooms damping that were produced on plants grown for no other object than home decoration, and which

thus it is that it is more prevalent in wet or foggy than in dry frosty weather. Where houses are not tightly glazed, and rain drips in upon the plants and flowers, the evil is also sure to be felt. Plants that have been grown within the shade of trees, or too near high walls, often lose flowers by damp, which proves that the want of maturity in the growth of such plants is in their case a cause of damping. Now as to the best treatment, not only to prevent damping, which arises from preventable causes, but to check it when brought on by means of manures acting on the roots. At all times—day and night:—

FIG. 72.—TENNYSON'S HOUSE, FARINGFORD, ISLE OF WIGHT. (SEE P. 457.)

roots are crippled, and are thus prevented from carrying out their proper functions. I have seen and experienced many cases of the kind, but one which was, perhaps, more striking than any other, occurred during the season of 1891, and may serve as an illustration. A well-known cultivator of Japanese blooms in the South of England had amongst his many fine blooms one of Mrs. Alpheus Hardy, and, wishing to improve the already fine flower, applied an extra strong dose of sulphate of ammonia, with the result that in two days the bloom was entirely spoilt, whereas if he had been content with an already good enough bloom, this experience would not have been obtained. Another instance I

had never received anything but clean water, with, perhaps, an occasional application of liquid manure from the farmyard?

Damping can be produced by atmospheric conditions only, but no one would so wilfully ignore simple details of management who had the least experience so as to spoil them in that way. If the temperature of the inside of any house is allowed to fall too low during the night, thus rendering the surface of the petals cold, the moisture in the house will naturally condense on it, and when in this state the sun should shine on them before the air in the house has been ventilated and artificial heat applied, damping is almost certain to follow, and

the air of the house in which the plants stand should be buoyant, and this can be secured by warming the hot-water pipes in dull or foggy weather, or furnishing a proper supply of fresh air when the weather permits. It is difficult to fix a certain temperature for Chrysanthemums, houses and situations varying so much, and it is much better if the grower be guided by the "feel" of the air on entering a house. If neither stuffiness nor chilliness strikes one upon entering, the air is all right.

Too much artificial heat renders the petals soft and flabby, and the flowers are spoilt in their final development, the grower ignoring the fact that Chrysanthemums are hardy plants and should receive

suitable treatment as such. Some persons think damping is caused by a lack of ventilation, and at once throw open the ventilators and doors as wide as possible, causing a direct draught. My advice is almost the reverse of this: Afford a fair amount of air, but in such a manner that draughts are avoided. Warm the hot-water pipes, so as to render the air buoyant, admitting fresh air freely, at the front if a lean-to house, and a little at the top, to let out excessive moisture. It is not the quantity of air that is applied that answers best, but the manner in which it is admitted. Shade is very important. The sun should not be allowed to shine directly on the plants after they commence to unfold their florets, especially if they have been highly fed, or the weather has been dull, rendering the florets flabby. The best kind of shade is a roller blind placed outside the house, no permanent shade being employed, or the colour of the blooms, if they are far from the glass, will be spoiled to a certain degree. The rule should be, no sun no shade.

The water draining from the pots, if the floor is non-absorbent, should be dried up as quickly as possible after watering. Decaying leaves and petals should be removed as soon as noticed, everything being done to render the air sweet and pure. It has been said that unslaked lime, kept in boxes or big flower pots, placed amongst the plants, would act as an absorbent of moisture, and in this way exert a beneficial influence by preventing damping, but not having tested its efficacy in this way, I am unable to say anything about it. Where damping is caused by the injudicious application of artificial manures, I should doubt the advantage of lime used in this way. *E. Molyneux.*

ROUND LIVERPOOL.

(Continued from p. 433.)

MESSRS. R. P. KER & SONS, AIGBURGH.—In this neat and well-kept nursery, we find a model of what a nursery should be when it is intended to grow well such things only as are in demand, and which can be grown to perfection in that particular nursery. The bane of many nursery gardens is the struggling continually to grow things which repeated trial has proved are not adapted to the place, or rather, for which the place and its accommodation are not adapted.

The outdoor and indoor departments are fairly balanced, so that it is difficult to say which is the more important, as Mr. Ranger, the clever manager to the firm, allows nothing to be neglected or carelessly done. At the entrance is a bright flower garden, about which stand some large standard and pyramid Bays. Beyond are the well-kept borders, and banks of rare shrubs, fronted by specimens of *Retinosporas*, and displaying a great wealth of variegated foliage, among which, remarkably striking, were *Syringa Emodi variegata*, *Cornus sibirica*, *C. Späthii*, *Corylus avellana aurea* and *C. purpurea*, *Hamamelis aurea*, and various forms of golden-leaved Alder, and other shrubs and trees. Among berry-bearing shrubs, *Cotoneasters* were remarked, and of the pretty genus, the purple-berried *C. Fontainesii*; while in all the broad beds the wealth of perfect, clean, and well-grown *Hollies* pointed to valuable stock, and gave present effect.

In the quarters are large quantities of things for forcing or for decoration in town. Among these, one of the most striking is a large patch of neat plants of *Rhododendron blandum*, a specialty here, and which is said to force easily to be in bloom at Christmas. The flowers, when forced, are nearly white, and the plant is distinct, and most floriferous. Other *Rhododendrons* are grown in quantity for the same purpose, but none come in so early as *R. blandum*. *Azalea mollis*, too, receives much attention, and the plants are compact, and covered with buds; and among the quantities of things grown for potting-up, were numbers of tree *Ivies* and other plants of a dwarf habit. A long row of young plants of the true *Balsam Poplar* was remarked. It is said that that usually planted under that name is the Ontario *Poplar*, which is inferior to the true one in many respects.

Glass-houses.—The main block consists of a lofty dome-topped central structure, and six ranges radiating from it, and communicating with the potting-sheds and other offices. The other houses in special blocks are of various heights and aspects, filled with sound, saleable plants. In the first large span-roofed house leading to the one in the centre, a fine lot of large *Camellias*, chiefly double whites, for cutting, *Carnations*, *Heaths*, *Heliotropes*, and other plants in flower, were found. In the second division, decorative *Palms*, *Grevillea robusta*, and some pretty plants of the variegated *Ficus elastica* which was sent out from this nursery.

Cyclamen persicum are done here equal to those seen in the London market, and several houses were full of these plants in a superb condition, the earliest of which were just beginning to flower. For the strain, it may be said that it is of the *C. p. gigantea* type, and the crimson varieties of an intensely bright shade of colour. *Amaryllis* are cultivated in large numbers, and show signs of careful hybridisation, the Aigburth stock exhibiting marked improvement, especially in the light colour, on some of the English and best continental strains which were bought to work upon. Of these bulbs, there are some thousands, in various stages, and in fine condition.

Pot and climbing *Tea Roses* follow in other houses entered; and in the tall central house, and in some of the other houses, *Kentias*, ranging from 1 to 10 feet in height, and in all the sizes, well-furnished, and wide-spreading in proportion to their height, were observed—a large and fine stock of plants.

The Aigburth *Crotons* are known all over the country for their fine colour and healthy development, and the houses are filled with such a great variety of brilliantly-coloured kinds that a selection becomes difficult. *Croton Golden Ring* is a charming thing, with foliage bright red and green at the base, which gradually change until the golden-yellow top is reached. *C. Aigburth Gem* is a very compact form of *C. interruptus*, with red, yellow, and green, beautifully blended in its graceful foliage; *C. Aigburthensis* has very handsome narrow, golden and green leaves, and is the best of the *C. angustifolius* class; *C. Hawkerii* and *C. Madame Heine*, which some complain of as being awkward growers, here branch out from the ground-level, and the foliage colours well; *C. Reidii* is very fine, and, indeed, grown as the *Crotons* are here, all were good.

Among the rest of the general stock, were noticed quantities of *Arancaria excelsa*, *Asparagus plumosus*, *Dracenas*, *Caladiums*, *Gloxinias*, *Begonias*, *Adiantum cucueatum*, and other *Ferns*, *Tillandsias*, *Ixoras* in bloom, *Pandanus Veitchii*, white and red *Lapagerias*, *Azaleas*, and *Heaths*.

Mr. Ker and Mr. Ranger, who conducted us round their well-appointed establishment, evidently had faith in the quality of the stock, for no word of praise was offered on their part, unless in reply to a question as to the merits of certain plants.

(To be continued.)

FORESTRY.

TREES FOR MARSH AND MOUNTAIN.

The Cluster Pine, *P. pinaster* (Aiton), is indigenous to different parts in the South of Europe and elsewhere, and was introduced into this country by Gerard about the end of the sixteenth century; and, although it has never been planted to any great extent as a timber tree for utility and profit, yet it possesses some qualities of no mean order, which ought to recommend it to the notice of the planter. Although it is one of our best Pines for planting on dry, sandy ground in marine situations, yet it is by no means confined to such, as I have planted it with perfect success on reclaimed marsh ground, peat-bog, and cold, stiff, adhesive clay-soils in inland districts of the country. I have seen it repeatedly stated that the Cluster Pine would not grow to a useful size on peat-bog and stiff clay soil, but this is an error, as I find trees that I planted on both classes

of soil upwards of thirty years ago to be in perfect health, and making rapid progress. Under ordinary circumstances, it attains a height of from 60 to 80 feet, with a uniform thickness of stem, which is generally free of knots or blemish of any kind for a distance of about three-fourths its height from the ground. When the wood is cut up for use it is found to be resinous, well-packed, and capable of being used for a variety of purposes. When planting this tree on loose sand, soft mossy ground, and peat bog, I have experienced considerable difficulty in getting the plants established, as they are generally deficient in side-roots, and are thereby easily upset by the wind; and when trees are not kept in a perpendicular position during the early stages of their growth, they are apt to form crooked stems, which detracts from their value for ornament and utility. Instead of planting this tree on such situations, I have found the best results by sowing the seed on the spot where the trees are to remain, as their strong tap-roots anchor them firmly to the ground, and they give no further trouble in this respect. On the other hand, when it is desirable to raise the plants in the nursery, the seed should be sown about the end of April on loose sandy soil, formed into beds 4 feet wide, and as it is best to allow the plants plenty of space to promote a bushy habit of growth, 1 lb. of seed should be allowed for every eight lineal yards of a bed the above size, covering them with about half an inch of fine pulverised soil. The seedling plants should be removed from the bed, and planted into nursery lines about 10 inches asunder, and the plants about 3 inches apart in the rows. This planting-out should always take place during the first autumn or spring after the sowing of the seed, and when the plants have been one season in the lines, they are then in condition to be transplanted to the forest ground, where they are to remain, but on no account should they be allowed to remain in the nursery for a longer period than two years after the time of sowing the seed. The contour of this tree is sharply conical, and when planted in blocks by themselves, they should be allowed more space than the Scotch Fir or Larch, otherwise they will spindle up into tall bare poles, which are comparatively useless as timber trees.

There are several interesting varieties of the Cluster Pine, one of the best of which is *P. P. Hamiltoni* (Tenore), which was first introduced into this country in 1825 by Lord Aberdeen. It is a true Mountain Pine, and is indigenous to the hilly parts of the country about Nice. As a variety, it certainly differs widely in many respects from the species. It makes a splendid specimen tree for the park or lawn, and as it is well clothed with leaves, branches, and spray, it is very attractive and ornamental all the year round, more especially in winter, when loaded with its large ovate-shaped cones, which are generally produced in pairs, whereas the cones on the species are of a smaller size, sharp-pointed, and generally produce in clusters, hence the name. Gordon, in his *Pinetum* (p. 250), tells us that the leaves of *P. P. Hamiltoni* are of a paler green colour than that of the species, but I have raised both kinds from home-saved seed in the nursery side by side, and found the reverse to be the case.

No doubt soil and climate may alter the appearance of the foliage to a certain extent; but in Great Britain and Ireland, under very different conditions as regards soil and climate, I have found the leaves of the species to be of a lighter green colour than that of the variety under consideration. The roots of this variety, however, are generally better furnished with small fibres than that of the species, and in order to promote its best form of development, the ground should be well broken up with a pick, and thoroughly drained, where requisite, before planting the trees, as they are very impatient of stagnant water at the roots. This variety is so widely different in its roots, stem, branches, foliage, size, shape, and arrangement of its cones, that I am strongly of opinion that it is no variety at all, but a very distinct species of itself. I have, however, had a very distinct variety of this Pine sent me under the name of *P. P. maritima*, which is very like the

species in many respects, and as it grows equally well under the same conditions, it is well worthy of being used by the planter. The cones of this variety are of a lesser size, and are produced in larger numbers than that of the species; its leaves also are less than those of the Cinster Pine. All the varieties are highly suitable for shelter, ornament, and utility in marine situations in the congested districts of Ireland, where it is desirable to establish covert and shelter within the influence of the sea breeze. When the trees are to be raised from seed sown on the spot where they are to remain, two people should be employed, one of whom should

Dormer family, but now in the occupation of Mr. Alderman George Nelson, of Warwick. The boundary of the parish is somewhat unique; its eastern one appears to be the middle of the track of the Great Western Railway, which occupies the old bed of the river Cherwell, for the accommodation of whose waters an entirely new channel was made by the railway engineers. Rousham is an ancient place, the Domesday Survey of 1086 mentioning it as being one of the possessions granted by William the Conqueror to certain of his followers. In the reign of Henry VI., Sir Thomas Chaworth is described as holding the manor of Rousham, and the

walks at Rousham in the garden of the Worshipful John Dormer, Esq., where there are no less than five, one under another, leading from the garden above down to the riverside (Cherwell), having steps at each end, parted with hedges of Codlings, &c.' These terraces, it is said, have ceased to exist, but there are still walks under noble trees leading down to the river banks.

An illustration is afforded at Rousham Park of a taste that at one time prevailed among noblemen and persons of wealth, viz., to adorn their estates with sham ruins, the Earl Bathurst of the period being in the van of this singular movement. Accordingly Sir Charles

FIG. 73.—BRIDGE IN THE LATE POET LAUREATE'S GARDEN, FARINGFORD. (SEE P. 457.)

break the surface of the ground here and there with a draw-hoe, while a second person drops a few seeds on the spot thus prepared, and finishes by giving the soil a scuffle with the foot, which is all the covering the seeds require. I have found the month of April the best time of the year for performing this operation. *J. B. Webster.*

ROUSHAM PARK, STEEPLE ASIITON, OXON.

THE village of Rousham borders on the Great Western Railway a few miles north of Oxford, and close by is the Park, and the family mansion of the

local chronicler, with a touch of sarcasm, remarks that "Chaworth appears to have somewhat resembled Lord Overstone, of whom it is said the difficulty is not to say in which counties he has real property, but in which he has not.

In May, 1635, the estate of Rousham was conveyed to Robert Dormer, and, notwithstanding the troublous times of the great rebellion, Rousham was speedily improved by its new proprietors, for in 1676 Dr. Plot described it as "one of the structures of the minor nobility," meaning, no doubt, the landed gentry, "that show a great deal of either of past or present magnificence." It was then the property of John Dormer, Esq., whose garden walks are thus described:—"For a descent, there are none like the

Dormer, the then owner of Rousham, erected on a piece of his freehold land a pile of rough masonry with three lofty arches, the centre one being the tallest and widest, intending, it is thought, to represent a part of the gate-house of a castle, or of a monastic building, though it was overlooked that semi-circular arches are inconsistent in structures of that date. This erection, which is visible from the railway, appears to have had a further utilitarian purpose, as, being in a direct line from Rousham House to Aynho House, it directed the eye to a system of flag signals, which the families adopted to signify absence and presence, and other telegraphic signals. Beyond this erection stands the mansion, which occupies the rising ground, and contains a mixture

of the ancient and modern. It is low, and somewhat heavy-looking; it occupies a considerable space of ground, and on one side lie the kitchens and other outbuildings, the laundries, stables, &c.; and, immediately contiguous to these, the church and small villages, the principal street of which is a cul-de-sac.

In the pleasure grounds and park are fine examples of Beech, Elm, &c.; Horse Chestnuts are also very fine indeed. The trees along the banks of the Chervell were already taking on to their foliage warm autumn tints. A broad stretch of sward on the north-east front of the mansion falls away to the pleasure grounds; on the south-west there are riband borders of bedding plants, with beds of Begonias that do admirably. The walls of the mansion are clothed in various places with creepers. A spacious conservatory is on one side of the mansion.

Rousham boasts an excellent kitchen garden, well walled-in, and, like the remainder of the grounds, admirably kept by Mr. H. Wingrove, the gardener. As a successful cultivator of kitchen garden crops, Mr. Wingrove takes high rank. It was here the famous Rousham Park Onion originated, which is a very fine form of the White Spanish or Reading. This and the Improved Wroxton are the two main varieties grown; the latter a fine reddish-brown Globe Onion, solid in the flesh, and an excellent keeper. Globe Artichokes do well at Rousham; the Ne Plus Ultra Runner Bean was very fine; near the Bean was a fine breadth of New Zealand Spinach. A line of Ne Plus Ultra Pea from a late sowing, and just coming into bearing at the middle of September, was remarkably free from mildew. Mr. Wingrove said it put in appearance, but by dusting the soil about the roots and the lower foliage with soot, it not only removed the mildew, but greatly helped the Peas. A large piece of the Improved Wroxton Brussels Sprout was very fine; and of Celery, Wingrove's Selected Aylesbury Prize Red seemed to be perfect.

On the walls Plums, Pears, Peaches, Nectarines, Apricots, &c., were largely grown. The Apple and Pear crops were thin. Bush fruits do well, and are somewhat largely grown. Strawberries grow well, and bring heavy crops; the two varieties mainly grown are Vicomtesse Héricart de Thury for an early forcer, and President to succeed it. These two are prominent in the open ground. Mr. Wingrove highly praises Vicomtesse as a forcer, and states that he can get thirteen and fourteen fine fruits on a plant at a time, not large, but well-coloured and finely-flavoured. The station for Rousham is Heyford, and the grounds are reached in a short time by a pleasant road. *R. D.*

THE ROCK GARDEN.

ERIGERON MUCRONATUS.

This is one of the most peculiar autumn-flowering plants I am acquainted with. When the blooms open, they are for all the world like common Daisies, but gradually the petals assume a pink tinge, which gradually deepens into a full rose colour, which renders it really a pretty object, with several colours on a plant at the same time. This Erigeron is very suitable for the rockery, growing but 4 inches high, with a somewhat straggling habit. *E. M.*

FRUIT REGISTER.

COE'S GOLDEN DROP PLUM ON A NORTH WALL.

The heavy crops of excellent fruit lately gathered from two trees of Golden Drop Plum growing against north walls, go to show the wisdom of the proverb, "Never to place all your eggs in one basket," inasmuch as trees of the same excellent Plum growing on south and east walls bore no fruit this year, the blossoms having been destroyed by frost, whilst the trees on the north walls, being late-flowering, escaped injury. *H. W. W.*

THE WEEK'S WORK.

PLANTS UNDER GLASS.

By R. MILNER, Gardener, Penrice Castle, Swansea.

SHOW AND FANCY PELARGONIUMS.—Plants which were cut back after blooming, and have broken away freely, may now be shaken out and repotted, before the young growths get much advanced. The older specimens should have most of the old soil shaken from them, and at the same time cut back any of the straggling roots, afterwards repotting them into pots one or two sizes smaller than those they previously occupied; and when the roots have penetrated freely to the sides of the pots, they should be shifted again into larger ones. A good compost for these plants is made of three parts turfy loam, one of decayed manure, which has been previously run through a fine sieve, and one of leaf-mould, with the addition of a little soot and sharp sand in sufficient quantity to keep the whole porous. Before potting, have the pots washed thoroughly clean, and perfect drainage added. Guard against overwatering until the roots have taken possession of the fresh material, as with light syringings overhead early in the afternoon on fine days, very little water will be required at this season of the year. Keep a sharp look-out for green-fly, and as a preventive, a light fumigation occasionally will keep them clear. Place the plants in a cool-house or pit, well up to the glass, giving them plenty of air on all favourable occasions.

ZONAL PELARGONIUMS.—Plants which have been grown specially during the summer for winter blooming should be removed forthwith into their winter quarters, taking care to clean plants and pots before taking them inside. Avoid overcrowding; leave sufficient space between each plant, that they may be examined before water is given. Keep the plants well up to the glass, and assist them occasionally with doses of clear manure-water. A temperature between 50° to 55° will be found suitable for them during the winter months.

LACHENALIAS.—These most useful bulbous plants may be grown by anyone having a structure where the temperature can be kept from 40° to 50°. No time should now be lost in turning the bulbs out of the pots in which they have remained during the resting period. Sort them into different sizes, which will ensure a uniform growth in the different pots. Three parts rich friable loam, one of leaf-soil, with a little decayed manure, and sufficient sharp sand to keep it porous, will suit them. Place the bulbs about three-quarters of an inch apart in the pots, afterwards covering them with about half an inch of the finest of the compost. When the potting is completed, plunge them in a cool frame, giving only sufficient water to keep the soil moist; and as soon as they commence to throw up leaves, give them plenty of air on all favourable occasions.

CALADIUMS.—These will now be getting past their best, and should be allowed to ripen off, withholding water for a time, so as to check the growth of the plants. Place them all together in a structure where the temperature during the autumn and winter months is not allowed to fall below 60°, as should they be kept in too low a temperature, the tubers will assuredly decay. Gesneras, also Alocasias (which die down to the root), Achimenes, and Gloxinias survive the winter best when treated like the Caladium.

THE KITCHEN GARDEN.

By G. WYTHES, Gardener, Syon House, Brentford.

POTATOS.—These will require more attention the first few weeks after storing than later in the year. If at all diseased when lifted they should be gone through weekly, as this work can be done in inclement weather. Early kinds, such as Myatt's Ashleaf and second earlies, especially large tubers, are often the worst keepers. Seed tubers should now be on their shelves, and kept cool by free exposure in fine weather.

CELERY should be earthed up on all favourable occasions, though, as I have previously explained, there need be no hurry with late kinds for spring use, as the frost does not injure the green tops when well hardened so much as it does blanched heads. A dressing of soot, salt, or fish manure will do much good before earthing up. I know of no better protecting material than thatched bundles made to fit the rows. If the weather is severe, dry leaves or

litter may be used in addition. For late rows I do not advise protection if a hardy medium-sized kind is grown.

CHICORY should be lifted, and stored up in the root shed, and they will give a supply of tops all through the winter if a few roots are placed in the Mushroom-house weekly. The Witloef is excellent for this purpose, and should be grown in all gardens, being one of our best and most readily grown winter salads, and of fairly good quality when cut about 4 to 6 inches, and served like Seakale. Leave about one inch of the base of the leaf stalks of Chicory. Salsafy and Scorzonera should be placed in the root store in moist soil, sand, or ashes. These are excellent vegetables, as they can be kept till late in the spring, and when used at that time are most valued. When stored in a warm place they shrivel badly, so that an outhouse is best, and the roots stocked with plenty of soil between them, just protecting from severe frost.

ARTICHOKES of the Globe section should have the loose leaves removed, and some short litter placed over the roots, cutting down the old flower-stalks to the ground; and in case the roots are large or weak, a dressing of manure or wood ashes before adding the litter will do good. Jerusalem Artichokes will now have completed their growth, and the tops may be removed, and the roots lifted for use if required, but these are best left till later. If protection can be given by covering the surface with litter to keep out frost, or a portion may be lifted and stored like Potatos, as then they can be readily got at in severe weather. The newer Artichoke, or Stachys tuberosa, is likewise best when left in the soil. It is quite hardy, but for convenience should get a little litter over the surface in severe weather.

CABBAGES, ETC.—No delay should take place in planting out the succession lot of Cabbages. These will be found serviceable in case any of the earlier sowing run. It is advisable to finish planting as soon as possible, and to plant a good number now, as this lot usually turns in early in May. Coleworts now will be plentiful. Some soil should be drawn up to the rows of those planted late for spring cutting. If any of the hardy green remain in the seed bed, they may be planted 6 inches apart each way, and will be useful in the spring, as these do not run so quickly as the Rosette.

The last planting of Endive should be made in places where protection can be afforded. The large-leaved Batavian sometimes succeeds in ordinary winters at the foot of a south wall or on a raised border. They are worth a trial, and in severe weather may be covered with boards, bracken, or litter. Those planted early will now be ready for use, and may be blanched by means of tiles, pots, or boards, or tied up, lifted, and placed in a dark house. The Endive in frames for later use should now be covered at night, and heavy rains kept off by the lights, at the same time giving abundance of air whenever possible.

THE ORCHID HOUSES.

By H. A. BURBERRY, Orchid Grower, Highbury, Birmingham.

DOUBLE-GLAZING FOR THE PHALÆNOPSIS-HOUSE.—Writing on protection from cold last week, I omitted what seems to me to be an important matter, so far as the general culture of Phalænopsis is concerned. We have the system of double-glazing here, both for Phalænopsis and East Indian Orchids, and find it invaluable as a means of keeping the temperature of a uniform warmth without the use of much artificial heat, and in completely preventing the condensation of moisture on the inner surface of the roof-glass—a frequent cause of watery spots appearing on the leaves, and which lead to loss of leaves or parts of them. Those who have hitherto been unsuccessful with these Orchids, should try this method of double-glazing, under which our plants do so well, of which there will be no doubt when I state that many of the leaves of Phalænopsis Schilleriana are from 12 to 15 inches long, and from 3½ to 4½ inches broad; while those of *P. amabilis* and *P. grandiflora* are proportionately large, and spotting of the leaves rarely occurs. In the south of England, or other favoured places, or where the houses are sheltered by art or Nature, double-glazing may seem superfluous; but in the Midlands and the North, if the houses are much exposed, double-glazing has great advantages. In this case, the lights should be constructed—using squares of glass of a large size—so as not to have a great number of sash-bars to obstruct the light; these should be fixed so that a space of 4 or 5 inches is left between the two roofs,

provision being made for top ventilation [and for thorough cleaning of the inner space, which becomes very dull in time, and which no amount of syringing will free from dirt. En.]

MANURING ORCHIDS.—Our plants, growing, as they needs must, under conditions more or less artificial, require something in the way of a stimulus to growth, and if this be afforded in moderation, and with due regard to the quality of the water used, whether it be river-water flowing through fertile lands, and necessarily more nutritious than well-water, or merely rain-water, much will depend on the health of the plants, and the nature of the compost in which they grow. Taking all these points into consideration, manure may be applied with advantage to Orchids, provided their ventilation is properly attended to. The important questions of when and how to apply it necessarily arise, and here, I fear, we too often work in the dark, and much has yet to be learned by observations and experiments carefully made. However, it has so far been proved beyond a doubt that weak manure-water made from cow-dung or sheep's droppings is of benefit to most Orchids during the growing season, and I have in previous Calendars recommended the use of this; but as the time is at hand when but little watering at the roots is required, the use of any kind of manure (unless in exceptional cases) should be stayed as far as using it in the water goes, merely sprinkling the paths the last thing at night with weak manure-water, which the plants absorb. For *Odontoglossums* and *Oncidium*s, there is no better stimulus than that afforded by soot and lime water in equal parts, about half a bushel of each being tied in a bag and put into a large tank or butt of water. Decaying sea-weed, tan, and hard tree leaves give off something that is much liked by *Phalenopsis*; and guano-water sprinkled on the floor of the *Cattleya* and *Lælia*-house assists the plants in finishing up their new pseudobulbs.

FRUITS UNDER GLASS.

By J. RIDDELL, *Gardener, Castle Howard, York.*

VINES that were early forced are now ready for their winter dressing, and may be proceeded with at once. Finer wood or more plump buds I have rarely seen than are met with this year, which may be taken as a good promise of fruit next summer. Where young rods are being run up to replace old ones, 3 or 4 feet of the current year's cane may be left, according to the strength of the wood, and all the spurs on the old canes corresponding with the same lengths may be cut off. Shorten all lateral growths to a plump bud, as near their base as possible. I may be allowed to remark here that the position of good buds on the shoots of Vines depends a great deal on the manner in which they have been trained. When the laterals are laid in at right angles from the main cane, the leaves at the nodes nearest to the spurs will retain their vitality throughout the season of the Vine's growth, and promising eyes for a future yield will be found close home. On the other hand, however, when the shoots have been placed in a slanting position towards the apex of the house, the leaves referred to fail to perform their functions during the time stated, with the result that their early decay is a bad augury of large bunches being obtained from shoots emanating from eyes formed at their base. The most striking examples of early leaf-falling of this kind are to be seen on young and vigorous plants, therefore it behoves the pruner to consider well the subjects upon which he is plying his skill, in order that the best crop obtainable may be secured. Thoroughly cleanse all wood, iron, and glass, with a hard brush and soapy water, and should mealy-bug have found a home within the structure, the canes may be got into bundles, and protected with waterproof waggon-sheets, and the whole of the roof-trellising, walls and ends, be well drenched with hot water, in which a fair proportion of soft-soap and petroleum has been added. In applying this cleanser, care must be taken to keep it well mixed by returning every alternate syringe-ful into the vessel containing it. In removing the sheets, see that the liquid remaining upon them is safely carried beyond the canes before it reaches the border. The oil is volatile, and quickly evaporates from the surface-soil. Strip the canes of all loose bark, but be careful not to injure the green layer beneath; then go over them with a stiff brush and Fir-tree oil. Paint the framework and trellising of the house, when it becomes dry, with white lead, sealing up all crevices to prevent the escape of any bugs which

may be concealed within them. All walls may be whitewashed with hot lime, and an endeavour made to fill every cranny with it. After slinging the Vines in their places, the next question to consider will be "what amount of surface soil should be removed from the border." This will have to be decided in each case by the condition of the border itself, and the position of the roots in it. In some instances the soil may be in anything but a congenial state for plant roots, and its almost entire removal become indispensable to success. In adopting this course, the first step should be to clear away the loose materials from the surface, to get quit of any bugs resting there, and gradually work downwards with forks, preserving all roots that are met with, keeping them moist and covered with mats, and finally relaying them in a bed of new materials, and well watering the bed. The roots can thus be got to within 6 inches of the surface, and if Thomson's Vine Manure has been freely mixed among the fresh ingredients, a happier state of things will be the reward of such labours when next time the plants are called upon to finish their crops. When an extreme renovation of this kind is taken in hand, it is better to change the soil by sections of something like 6 feet by the width of the border at one time than by gradually lowering the whole length and width at once, as their roots can be a shorter time exposed. Borders in better form need only be reduced a few inches, till roots are found, and then be surfaced with a layer of lime, and then fairly well-rotted leaves, mixed with Vine-manure. Finish all such work by giving the borders a watering in keeping with their requirements.

THE FLOWER GARDEN.

By H. W. WARD, *Gardener, Longford Castle, Salisbury.*

RE-ARRANGING HARDY PERENNIAL PLANTS.—It takes some years to get hardy perennial plants properly distributed in herbaceous borders; the dwarfier subjects may require to be brought nearer to the front, and the taller placed further back. The colours of the flowers must also be borne in mind in re-arranging the plants, and the clashing of colours in plants in proximity to each other averted as much as possible. These matters alone require a re-distribution of perennial plants; and then the height to which the plants grow must be considered. The present is a suitable time for doing this kind of work, the plants being in many cases still in flower, rendering replanting an easy matter. Take up the placed plants with good balls, and drop them carefully into holes made large enough to take the balls of earth and roots comfortably; tread the soil round about them, and afford water at the roots immediately afterwards. When the work is so performed, the plants feel their removal very little.

LIFTING AND STORING ROOTS.—Take up and store in a dry, cool place, in sand, the roots of *Dahlias* and *Cannas*. If the latter are growing in a high, dry, and well-drained situation, and the beds can be covered with a layer 3 or 4 inches thick of sifted coal-ashes, they will generally survive the winter. The tubers of *Begonias* are best wintered in a cold pit, laying them in sandy soil, with a good length of the tops adhering, and covering the glass with Fern in severe weather.

GENERAL WORK.—Gravel and turfed walks must be kept free from weeds, moss, and leaves, advantage being taken of moist weather to weed, and roll the weeded walks directly after the work is done. Where domestic fowls, pheasants, &c., frequent the walks, poisonous weed-killers must not be applied.

THE HARDY FRUIT GARDEN.

By H. MARKHAM, *Gardener, Mereworth Castle, Maidstone.*

STRAWBERRY BEDS.—These should be put in good order when the soil is in a moderately dry state, removing all late flower-spikes, runners, weeds, &c., so that no further attention will be needed till the spring. If the beds were thoroughly mulched with good manure, the plants will have made good crowns, and a fine crop of fruit next year may be anticipated. But where this precaution has been neglected, it should be done without delay. On light soils, the beds should be heavily manured twice yearly, i.e., in the early spring, and again when the crop is gathered. When mulching the beds, place some manure as close as possible to the plants. The beds should be relabelled with stout durable labels.

CUTTINGS OF BUSH FRUIT.—This is the best month in the year in which cuttings of Gooseberries,

Black, White, and Red Currants, may be put in, the cuttings callusing early, and making rapid headway the first year, and with but little loss. The cuttings should be made of the matured wood, shortened to 14 inches in length; if a heel to each, so much the better. Take out a few of the lower buds of all except those of Black Currants. Prepare a bed in an open spot, and set out the pieces at 12 inches apart between the rows, and 9 inches in the rows. The cuttings may be dibbled in, resting the base of each on a firm bottom, and filling the hole firmly with fine soil. But where many cuttings are struck it is better to open trenches 9 inches apart, and as much in depth, and lay the cuttings in these in an upright position, treading the soil firmly about them before finally filling in. Red and White Currants may be prepared and put in as for Gooseberries, but the buds, which come underground, should not be cut out; and keep free from weeds.

THE APIARY.

By EXPERT.

CANDY FEEDING.—It being now too late to feed with syrup, any stocks that have been overlooked and have not sufficient stores to winter on, should be provided with candy. When made, the candy is better run into boxes, either of wood, or cardboard, which must be inverted over the feed-hole, this being more convenient than putting cakes under the quilt. It would be a good plan to make a rule of putting a narrow box, filled with candy, on all stocks, a corresponding flap, along the middle of the quilt, at right angles to the frames, being cut for it, and turned back, as by this means the all-important winter passages would be assured.

A GOOD SYSTEM.—The season having come round when little can be done for the welfare of the bees outdoors, now the long evenings are with us, it is time to think of commencing to plan and prepare for another year's work. A good system of management contributes as much to success in bee-keeping as it does in other undertakings. The following is the outline of a system which the writer feels certain, if generally followed, would be productive of the best results. It is a modification of a plan recommended by Mr. Simmins, in his book, *A Modern Bee Farm*, and its importance seems to have been overlooked. The adage so well known to beekeepers, "keep all stocks strong," is what we all aim at, but which we find so difficult to accomplish. We will first of all suppose that the beekeeper has his full complement of stocks, and does not wish to increase the number. To carry out the system advocated, he must provide as many small, or nucleus hives, to contain six frames each, to be able to stand one at the side of each stock. When a stock swarms the nucleus hive is brought into use, as four of the frames, containing adhering bees, and at least one queen cell, should be taken from the swarmed hive and put into it. This makes room for the swarm to be returned to its original hive, after, of course, frames containing full sheets of foundation have taken the place of those abstracted, and all remaining queen cells have been cut out. The swarm will soon be at work filling the supers with honey, and no after-swarms will issue, whilst the nucleus at the side will soon contain a young fertile queen, and will increase considerably by the autumn, when the old queen must be removed from the parent stock, and the two united. If this plan be followed, it ensures a young queen for each hive every year, and doubles the population after the wear and tear of honey gathering and syrup storing has taken place. Provision would have to be made for some hives not swarming, which could be done by making in some cases two nuclei instead of one.

CHICAGO EXHIBITION.—In 1822 a patent was issued to Jeremiah Bailey, of Pennsylvania, for a mowing machine, and he constructed two machines the same year. It is believed that these were the first ever made. A number of years later a patent for improvement on this machine was secured, and some fifty of the improved machines were built. Only two of the original pattern were ever made, and one of them is still in existence, owned by Samuel Worth, of Marshallton, Pa. He will exhibit it at the World's Fair, where, as a pioneer in agricultural machinery, it will attract much attention. The knife of the machine is circular, and had a combined rotary and forward motion.

EDITORIAL NOTICES.

LOCAL NEWS.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Advertisements should not be sent to the Editor, but to the Publisher.

APPOINTMENTS FOR THE ENSUING WEEK.

SALES

MONDAY,	OCT. 17	Great clearance sale of Nursery Stock at St. John's Nurseries, Worcester, by Protheroe & Morris (five days).
TUESDAY,	OCT. 18	Clearance sale of Nursery Stock at Sea View Nurseries, Havant, by Protheroe & Morris. Sale of Dutch Bulbs and Imported Orchids at Protheroe & Morris' Rooms. Dutch Bulbs, at Stevens' Rooms.
WEDNESDAY,	OCT. 19	Sale of Nursery Stock at the Sunningdale Nursery, Berks, by Protheroe & Morris (three days). Clearance sale of Palms and other plants at Hackney by Protheroe & Morris. Sale of Dutch Bulbs at Protheroe & Morris' Rooms. Liliums and Lily of the Valley, at Stevens' Rooms.
THURSDAY,	OCT. 20	Sale of Dutch Bulbs and Greenhouse Plants at Protheroe & Morris' Rooms. Orchids, &c., at Stevens' Rooms.
FRIDAY,	OCT. 21	Sale of Orchids and Dutch Bulbs at Protheroe & Morris' Rooms.
SATURDAY,	OCT. 22	Sale of Dutch Bulbs at Protheroe & Morris' Rooms. Spiraeas, Plants, &c., at Stevens' Rooms.

SHOW.

TUESDAY,	OCT. 18	Royal Horticultural Society at Drill Hall, James Street, Westminster, Lecture at 3 P.M. on Cycads.
----------	---------	--

MEETINGS.

THURSDAY,	OCT. 20	Brighton and Hove Chrysanthemum Society.

CORRECTED AVERAGE TEMPERATURE FOR THE ENSUING WEEK, DEDUCED FROM THE OBSERVATIONS OF FORTY-THREE YEARS, AT CHISWICK.—49°·8.

WILLIAM HARDWICK BRADBURY.—We receive the sad intelligence, as these sheets are passing through the press, of the death of Mr. WILLIAM HARDWICK BRADBURY on the 13th inst., in the sixtieth year of his age. Mr. BRADBURY was head of the eminent firm of BRADBURY, AGNEW, & Co. Ltd., Printers, Whitefriars, and one of the proprietors of this journal.

A SHORT time since we quoted, from an American source, an account of the forcing of Lettuce plants by the electric light as a commercial speculation. The usual results followed. At first blank denial, next ridicule, then the figures were challenged, but ultimately they were found to be correct. In due time we have no doubt whatever that we shall find the electric light taking its place among the requirements of horticulture as hot-water pipes do now, and then the usual thing will again happen, and we shall be told that this matter was perfectly well-known years ago! In order to bring about this consummation, we append the summary which Professor L. H. BAILEY, the eminent American horticulturist, gives at the end of his second report upon Electro-Horticulture, published in the *Bulletin* No. 42 of the Cornell University Agricultural Experiment Station.

"1. The influence of the electric arc-light upon greenhouse plants is greatly modified by the use of a clear glass globe, or the interposition of a glass roof. Plants which are much injured by a naked light, may be benefited by a protected light.

"2. As a rule, plants are earlier under the electric light than when grown in ordinary conditions.

"3. The light can be suspended above the house with good effect.

"4. Lettuce is greatly benefited by the electric light. An average of five hours of light per night hastened maturity from a week to ten days, at the distance of 10 and 12 feet. Even at 40 feet, in only diffused light, the effect was marked. The light appeared to injure young newly-transplanted plants.

"5. Radishes were also benefited by the light, but not to a great extent. When the light was hung in the house, however, whether naked, or protected by a globe, Radishes were injured.

"6. Beets and Spinach appeared to be slightly benefited by the light.

"7. Cauliflowers under the light tended to grow taller than in ordinary conditions, and to make fewer and smaller heads.

"8. Violets and Daisies bloomed earlier in the light house. This corroborates results obtained with other flowers in our earlier experiment.

"9. The electric light does not appear to determine or modify the hours of growth of Lettuce and some other plants which have been studied in this particular. Plants which are benefited simply grow more rapidly during the customary periods.

"10. I am convinced that the electric light can be used to advantage in the forcing of some plants. L. H. Bailey."

As a further contribution to this matter, so important for the horticulturists of the near future, we subjoin a brief account of M. GASTON BONNIER's recent experiments in Paris, as given in the *Comptes Rendus*.—

We read in the *Comptes Rendus de l'Académie des Sciences*, for September 19, that two lots of similar plants were exposed, one to continuous electric light, the other to the same light from six o'clock in the morning to six at night, and to darkness from six o'clock at night to six in the morning; a third lot in the open air, growing under ordinary normal conditions, served as a control. Owing to the arrangement of the space, the plants exposed to continuous and to interrupted electric light were kept in a uniform temperature, 13° to 15° C. (55° to 59° F.), and in still air. The light was furnished by arc-lamps, in globes, and the plants mentioned in this paper were placed under glass. The surroundings rendered it impossible to experiment with very species of plants; those which were found most available under the circumstances were bulbous plants, grasses made to germinate on the spot, submerged aquatic plants, and ligneous species.

1. *Comparison between continuous electric light and normal light.*—The shoots of the trees submitted to the continuous light, Austrian Pine, Silver Fir, Beech, Oak, and Birch, were very green, the leaves less dense than under ordinary light and less firm in general texture. At first sight, the shoots appeared at once blanched and rich in green matter [?], but it is known that in blanched shoots produced in darkness, the stems are at once thicker and longer, while the leaves are fewer in number; but in this case, on the contrary, the stems were in diameter almost equal to those of the normal plants and the leaves covered an equal surface, being by compensation slightly longer.

Speaking generally, these stems, although rich in chlorophyll and assimilating vigorously (as is proved by the quantity of oxygen given out under the previous trials), showed in their tissues less development than do the normal shoots.

Certain modifications in the anatomical structure were very noticeable, and far more marked than those usually found in specimens exposed to diffused light only.

Thus, a leaf from the centre of a shoot of an Austrian Pine, when cut across and compared with a similar section of an analogous normal leaf, exhibits the following peculiarities:—The epidermis has thinner and not ligneous walls; the sub-epidermis is slightly thickened; the cortical cells containing the chlorophyll grains is less developed as regards the central tissues, and the walls of these cells have not the peculiar folds so characteristic of the genus *Pinus*, and which are highly developed in the

normal specimen; the resin-canals are less than half the size, and are close to the sub-epidermic layer; these cells of the endoderm resemble those of the pericycle near them; the areolar tissue is less defined, and the two bundles, by which the wood and liber are distinguished, are as much as five or six times further removed one from the other than they are in normal specimens. The leaves of the Silver Fir, and Spruce, showed analogous modifications; those of the Beech, Oak, and Birch showed, in the palisade, the epidermis, and the stomata, less differentiation than did the similar but normal leaves, while they resembled the latter in the construction of their conducting tissue.

As for the stem, on examination of a transverse section made in the centre of a shoot of Beech grown under continuous electric light, and comparison of it with an analogous section of a similar shoot of the same tree grown under normal conditions, this is what is remarked. The woody bundles are as large as in the normal stem, but remain longer isolated one from another; there is a complete absence of the woody cells which form, in a normal specimen, a distinct and continuous ring, and is a marked characteristic; the cuticle of the epidermis is very thin, &c. Analogous changes of structure are noticeable in the stems of the Oak and Birch. The stems of Pine and Spruce show modifications more or less similar to those noticed in the leaves of those trees.

As to the diameter of the pith, which is so much augmented in blanched plants [Rauwenhoff, *Sur les Causes des Formes Anormales des Plantes qui croissent dans l'Obscurité* (*Ann. des Sciences Naturelles, Botanique*, 6th series, t. v., p. 266)]. It is not relatively larger in stems grown under continuous light.

Further study of the organs, undertaken at a more advanced stage, showed M. BONNIER that, under continuous light, not only is there a retardation in the formation of the tissues, but the structure is even appreciably different to that observed in plants under ordinary light.

2. *Comparison between Continuous and Interrupted Electric Light.*—Without entering into details, M. BONNIER states that the structure of organs subjected to this interrupted light, 12 hours dark, 12 hours with light, manifested a tendency to resemble that of the same plants grown under ordinary conditions. This final series of observations shows that it is not merely the nature of the light employed, but also its continuity, which influences vegetable structure.

Plants grown under continuous light, which assimilate uninterruptedly, and always in the same degree, are, as it were, disturbed in the utilisation and final differentiation of the assimilated matters. This differentiation cannot be maintained, under this perpetual daylight, as it is in ordinary plants during the night, or even during the comparative obscurity to which they are subject at high elevations.

To sum up, it may be said that—1. Under continuous electric light, considerable modifications of structure are induced in the leaves and young stems of plants.

2. The plant can be induced to respire, assimilate, and transpire day and night with unvarying regularity; it then seems embarrassed by this continuous action, and the tissues become more simple in structure.

3. The interrupted electric light (with twelve hours' darkness in every twenty-four) induces in the various organs a structure more closely resembling the normal condition than that induced by continuous electric light.

With reference to herbaceous plants, M. BONNIER states that:—

"The experiments were made on very varied plants—Hyacinths, Chinese Primroses, Pelargoniums, Tulips, Crocus, Myosotis, &c.; on cereals, Flax, Cress, Potato, *Stachys tuberosa*, &c.; also on numerous species belonging to the genera *Primula*, *Ranunculus*, *Hieracium*, *Taraxacum*, *Veronica*, *Anemone*, *Polygonatum*, *Helodea*, *Po-*

tamogeton, Ceratophyllum, &c. As has been before noticed in cultural experiments made with electric light (HERVÉ MANGON, 1861; SIEMENS, 1880; DEHÉRAIN, 1881; experiments at the Cornell University, 1890-91), a certain proportion of the plants died, some even under interrupted light, but many more which were subjected continuously to the light. A certain number of plants grown under glass in continuous electric light manifested, on the contrary, an exuberant development, with much more intense green foliage and darker coloration of flowers. Analogous modifications to these are

anatomical and structural changes which his specimens underwent, which in detail would not interest our readers. The following, however, are the general results observed by him. That—

"1. When the continuous electric light, under glass, produces excessive development of an herbaceous plant, with intense greening, the structure of the organs is at first greatly differentiated; but, if the electric light is intense and prolonged for months, without interruption or diminution, the new organs formed by the plants which are able to adapt themselves to this light present remarkable modifications

hybridum seen at the Manchester summer show will not be without use:—

"A passing reference was made in the *Gardeners' Chronicle* to the magnificent display of Rhododendrons shown in the Botanical Gardens, Manchester, by Messrs. JOHN WATERER & SONS of the American Nursery, Bagshot. Those who are acquainted with the building known as the Annexe will scarcely be surprised to learn that something like 2000 plants were grouped here, down the centre in the form of circles, with here and there a huge

FIG. 74.—GARDEN VIEW, CASTLE LEVAN, GOUROCK, N.B. (SEE P. 468.)

observed in plants at high elevations, and have formed the object of researches undertaken in Norway with M. FLAHAULT, which proved that light was the principal cause of this remarkable phenomenon.

But under the conditions under which M. BONNIER worked at the Halles, where the light was intense and too prolonged, the greater part of the plants, after this rapid development, seemed to suffer from an uninterrupted excess of assimilation. However, certain species of plants were able to adapt themselves to their exceptionable conditions. These were, as before mentioned, bulbous plants, grasses raised from seed, arborescent species, and submerged aquatic plants."

The author next gives a technical account of the

of structure in their various tissues, and are less differentiated, simpler in structure, but always rich in chlorophyll.

"2. The direct electric light is prejudicial, owing to its ultra-violet rays, to the normal development of the tissues, even if the lamps are more than 6 feet away from the plants."

Rhododendrons
at Manchester
Show.

MANY of our readers will doubtless be contemplating the planting of Rhododendrons from the nursery, or rearranging those that they possess at this season, and a few notes by an expert of the fine varieties of Rhododendron

stand, and forming the central objects, alternated in a few instances with a circular group of beautiful Japanese Maples. The sides were wholly formed of Rhododendrons, the varying shades of colour being alternated with admirable skill. The head of bloom was remarkably good throughout. The best varieties in the Bagshot collection were represented here, and the whole formed a display probably never before equalled in Manchester. The intense heat of the weather in the early days of June, intensified by the absence of an awning on the roof, took rapid effect upon the plants, and somewhat affected the duration of bloom, which in a cool time would have been much prolonged.

A selection made from the large number of

varieties found at Manchester would include some of the very finest in cultivation, such as *Album elegans*, a very good white; Baron Schroder, plum-purple, with a yellowish centre—very distinct, and quite late in flowering; Baroness Henry Schroder, white, very handsomely spotted on the upper segments—large, very fine, good habit and hardy; Broughtoni, rosy-crimson, very fine and striking; *Campanulatum pictum*, pale lilac, with reddish markings; *Cynthia*, rosy-crimson, very effective; *Duchess of Bedford*, crimson, with light centre; *Duchess of Connaught* white, with lemon-coloured markings—flowers of very fine quality borne on large bold trusses, extra fine; *Duleep Singh*, a very distinct variety of a dark chocolate-crimson colour—extra fine; *Everestianum*, rosy-lilac—an excellent grower, and carrying abundantly large trusses of bloom; *Frances B. Hayes*, extra fine white, the upper petals marked with maroon-crimson—excellent habit; *Frank Gower Waterer*, fine dark scarlet; *Generis*, purplish-claret, shaded with scarlet—very distinct and fine; *George Hardy*, a very good white; *Hector*, deep rosy-crimson; *John Henry Agnew*, one of the very finest, pale blush in colour, the upper segments finely marked with bright chocolate—very large truss, some will measure 15 inches across; *John Walter*, rich crimson, extra fine; *Lady Eleanor Cathcart*, an old but extremely striking variety of a bright rose colour; *Lady Olive Guinness*, clear white, with dark markings; *Lord Eversley*, intense dark scarlet-crimson; *Mrs. Heywood*, blush, edged with bright pink—very fine; *Madame Van du Weyer*, rosy-crimson, extra fine; *Michael Waterer*, probably the most strikingly coloured *Rhododendron* in cultivation, the colour bright scarlet-crimson—extra fine habit; *Mrs. Hemans*, delicate blush, very fine; *Mrs. William Agnew*, pale rose, deeper on the petal edges—a very fine and effective variety; *Nero*, rich bright purple, extra fine; *Pelopidas*, crimson, very fine; *The Queen*, still one of the best whites; *Sir Robert Peel*, very bright crimson, with dark spots; *Toward*, pale purple; and *William Ewart Gladstone*, deep rose, large trusses—extra fine.

Of new varieties, one of the most attractive was *Samuel Barlow*, blush-pink, edged with pale rose, the upper segments marked and blotched with yellow; this is a very hardy variety, said to have been obtained by a cross with *R. maculatum*. *Charles Waterer*, vivid crimson, is also very fine and striking.

Standard *Rhododendrons* are attractive objects in positions suited to them, and especially in the case of a large exhibition like that at Manchester. It is varieties which form bushy, close and handsome heads, that are suited for standards, and only a comparatively small number are so trained. A dozen of the best will be found in *Alexander Adie*, brilliant rosy-scarlet; *Barclayanum*, clear rosy-crimson; *Brayanum*, vivid crimson; *Concessum*, lightly margined with rose; *Hector*, *John Waterer*, rich carmine; *Lady Eleanor Cathcart* and *Minnie*, white tinted with mauve, large orange spots; *Mr. John Penn*, salmon-pink; *Nero*, *Sir Robert Peel*, and *Sir William Armstrong*, very light crimson, extra fine. As *Messrs. Waterer & Son* state, "of all the plants we know for single specimens on lawns, we believe nothing can compare with a standard *Rhododendron*; thoroughly hardy as they are, with their extremely handsome green foliage, they are magnificent through the winter, and in the last weeks of May and beginning of June, they unfold their buds, with colours varying from white, scarlet-rose, &c., and when fully developed, their beauty is such as must be seen to be appreciated," and when it is remembered a large and well-developed standard *Rhododendron* will sometimes have as many as 2000 bloom buds on the plant, some idea of the effect they produce in spring may be imagined.

Going from this grand display at the Botanical Gardens to Stakehill House, some 10 miles farther north-east, one could see in *Mr. Samuel Barlow's* garden *Rhododendrons* in not a few instances almost denuded of leaves, owing to the severity of the past two winters, and yet bearing on the points of their leafless shoots, trusses of good bloom. Perhaps on

no spot within 10 miles of the city of Manchester, would there appear to be centred so many influences hostile to vegetation.

Those who will grow the *Rhododendron* well in or about towns like Manchester, Sheffield, Newcastle, and some others, must endeavour to afford the plants by means of suitable soil, either peat or light fibrous loam, every encouragement to growth. To do this, in localities with a light rainfall, the plants should receive a few thorough waterings from the time they commence to grow in the early summer till the flower-buds are prominent on the tips of the shoots. In addition to watering these shrubs, a slight mulch of spent manure, leaf-mould in a partially-decayed state, or their own foliage which has fallen left under them undisturbed, and a little peat or loam scattered over it to keep it from being blown away, would afford them a nutritive mulch. Strong manures, which are rather inimical to the well-being of the plants, should not be given, and even manure-water is not a desirable aid to growth. Neither should digging ever be done in a *Rhododendron*-bed, except when the plants are young, and the roots are still close at home. It is usual to have an edging of *Ledums*, *Kalmias*, *Veronicas*, *Ericas*, *Menziesias*, *Zenobias*, *Pernettyas*, and *Gaultherias*, as a grading down of the *Rhododendrons* to the surrounding level of the ground; and these different species will require the same kind of treatment as the latter; but, with the exception of *Gaultherias*, *Veronicas*, and, perhaps, *Pernettyas*, the other plants should not be planted where there is much soot deposit, being short-lived. In this case, the *Rhododendron*-bed may have a wide margin of ordinary soil, which may be cultivated like any other ordinary bed intended for bulbs and spring and summer flowers.

GARDEN VIEW, CASTLE LEVAN.—In our engraving under the above heading (fig. 74) is depicted a homely kind of garden scene, of which many exist in localities in which the American plants find a congenial soil, and sufficient moisture to produce a vigorous growth. Our correspondent has not furnished us with the name of the variety, but it is doubtless one of the *Rhododendron* hybridum section, and our readers may, if they please, give it any one of the names of that numerous progeny, for which thanks are due to the intelligent efforts of hybridisers, such as *Messrs. C. Noble, Standish, Smith of Newry, the Waterers*, and others. In the mild climate of the west of Scotland, where the conditions are so favourable for the cultivation of *Rhododendron ponticum* and its varieties; *R. Catawbiense* and *R. caucasicum*, and its varieties *album*, *flavidum*, *Nobleanum*, and *pulcherrimum*, many of the species from the Himalayas, and hybrids raised from them, are grown with success; and in the warmer spots, not much exposed to the early morning sun, Indian species, like *R. arboreum*, and its varieties *album*, *cinnamomeum*, *roseum*, *limbatum*, and *puniceum*; *R. Nuttalli*, and *R. ciliatum*, a plant with pale reddish-purple flowers and leaves 2 to 3 inches long, pilose on the upper surface, the plant growing about 2 feet high. The late Captain *Mangles* cultivated most successfully in the dry climate of Haslemere, Surrey, on high ground, most of those above mentioned, and many others of Indian or Sikkim origin, by the simple expedient of retarding the growth of the plants by means of matting spread on a frame over them, or by placing them where the sun could not reach them, and keeping the shade on the plants till all danger from late frost had passed by. For a list of some good hybrids of *R. ponticum*, we may refer our readers to preceding Article, "*Rhododendrons at Manchester*."

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the Society will be held in the Drill Hall, Westminster, on Tuesday, October 18, in the

afternoon at 3 o'clock. *Mr. W. Carruthers, F.R.S.*, the chief of the Botanical Department at South Kensington Museum, will deliver a lecture on "Cycads," to which interesting class of plants he has devoted special attention. Growers of Apples, Pears, and Grapes, who intend to compete for the prizes offered in the Society's schedule, are requested to communicate the nature of their exhibit to the Superintendent, the Royal Horticultural Society's Gardens, Chiswick.

HORTICULTURAL CLUB.—The first meeting of the session 1892-93 will take place on Tuesday, October 18, at 6 p.m. The subject for discussion will be, "The Principles of Root-pruning Fruit Trees," to be opened by *Mr. George Bunyard*.

CHISWICK GARDENS.—A number of the later species and varieties of perennial *Asters* are still blooming in the Royal Horticultural Society's Gardens, Chiswick, where there is to be found probably one of the most complete collections of these plants in the world. They are well worth a visit from all lovers of the Starwort family. The collection of Apples has been stored in the fruit-room, and as each variety is correctly named, the attention of Fellows and others interested in the cultivation of the best kinds suitable for particular purposes, is called to the fact. The Grapes in the large conservatory are now ripe, and the big hanging clusters present a remarkably fine appearance.

OCTOBER HORTICULTURAL MEETING AT GHENT.—A Certificate of Merit for blooming was awarded to *M. Jules Hye*, for a *Renanthera Lowii* with two long racemes of fine flowers. Certificates of Merit for novelty were awarded for the following plants:—1, *Carex europæa* var., to *M. Ed. Pynaert*, little known in Belgium, though well worth cultivating; 2, *Canna Madame Crozy*, to *M. L. Desmet Duvivier*; 3, *Epidendrum Frederici Guilielmi*, to the same—an old Orchid, but shown for the first time at Ghent; much admired for its pretty colouring. 4, *Begonia striata formosissima*, to *MM. Blanquaert et Vermeire*, a pretty novelty, red, streaked and veined with white; 5, *Cattleya Gaskelliana marmorata*, to *M. Alf. Van Imshoot*, a pretty variety; 6, *Pteris cretica albo-lineata multifida*, to *MM. Duriez Frères*, remarkable for the great size of its pinnales and pretty colouring; 7, *Cypripedium Van Imshootianum* (hyb. *Chantini* × *callosum*), to *M. Moens*, of Lede, with a large and well-marked lip. Certificates for culture were awarded for—*Asplenium nidus avis*, to *MM. Duriez Frères*, an excellent specimen, in good health; *Croton magnifolius* var., to *M. Jules de Cock*, leaves large, and of a good colour; *Solanum jasminiflorum*, to *M. Alex. Dallièr*. Honourable Mention was allotted for *Odontoglossum Inseyanum splendens flavidum*, to *M. A. Van Imshoot*; and *Cypripedium insigne* × *Alburtonii*, to *M. Moens*.

WEED MAPS.—It appears that the German educational authorities appreciate the desirability of hanging in the elementary schools of Germany maps of the common weeds of the district, so that the children attending the schools may become acquainted with the appearance of the plants, the flower, seed, and its method of distribution, roots and leaves, &c.; and to prevent the waste of labour now incurred by adopting the wrong methods in extirpating weeds, the children are taught the readiest means of dealing with them. The children are also taught which weeds are hurtful, which of value as food, medicine, &c. Something of the kind should be included in the teaching in our rural schools.

A PELORIANTE DENDROBIUM PHALÆNOPSIS SCHRODERIANUM.—A beautiful flower of a peloriate form of the above plant, resembling that illustrated in our issue for November 28, 1891, p. 643, comes from the gardens of *Geo. C. Raphael, Esq.*, Castle Hill, Englefield Green. At first sight the flower bears more resemblance to an Irid than an Orchid. Such freaks are interesting, and there is a tendency in the plants which bear them to prove constant. The double form of *Epidendrum vitellinum* sent by

the same gentleman some time ago has flowered twice since, and on each occasion the flowers have been more double than before, and the form of *Cypripedium philippinense*, with triaepalous flowers, with the lower sepals divided and divergent, in the same gardens, is reported to remain constant.

CHRYSANTHEMUMS GRAFTED ON PYRETHRUM FRUTESCENS.—A Ghent amateur, M. ALEXIS DALLIER, has grafted Val d'Andorre, Etoile de Lyon, Paul Fabvre, and one of its white seedlings, on Pyrethrum, and the results have exceeded all expectation. Val d'Andorre is 6½ feet across, and bears 380 flowering-stems; Etoile de Lyon is 5 feet across, with 150 stems; the seedlings are 6½ feet across, and Paul Fabvre has more than 300 blooms. Besides these fine specimens, M. CALLIER has grafted some fifty others, all more sturdy than those raised from cuttings. All varieties are not adapted to this style of culture. We may add that the grafts were made in January, February, and April of this year.

CHEIRANTHERA PARVIFLORA is an elegant twining plant of the Pittosporum family. Its leaves are sessile linear, 1 to 2 inches in length; the flowers are on long slender peduncles, each flower ¼ to ⅓ inch in diameter, with minute sepals and obovate violet petals. It is figured and described in the *Botanical Magazine*, t. 7261.

POTENTILLA SALESOVIANA.—This is a shrubby Potentilla, with unequally pinnate leaves, silky on the under surface, and white flowers. It is a native of the Kashmir, Altai, West Tibetan and Thian Schan mountains, and is illustrated in the *Botanical Magazine*, t. 7258.

MONODORA GRANDIFLORA.—This is a West African tree of the Anonad family, with oblong-acute leaves, pinkish on the under surface, and long-stalked, drooping flowers. Each flower is 3 to 4 inches in length, with three reflexed lanceolate sepals, three outer petals, each 3 to 4 inches long, green, marbled with reddish-brown, and undulate at the edges; the inner petals are about half the length of the outer, broadly ovate-acute. The flowers are beautiful, and have a striking, though quite superficial, resemblance to those of *Gloriosa*. *Botanical Magazine*, t. 7260.

LECTURE ON HORTICULTURE AT QUORN.—On Saturday evening a Lecture on Horticulture was delivered in the large room at the Quorn Mills by Mr. J. W. WALKER, lecturer to the Leicestershire County Council, this being the first of a course of four lectures to be given during the present month. Mr. JOHN D. CRADOCK, secretary to the Quorn Hunt, presided, and there was a large audience. The subject was "Soils and Manures, their Uses and Abuses." The Chairman, in introducing the lecturer, pointed out the great need for technical education.

NATIONAL AMATEUR GARDENERS' ASSOCIATION.—The monthly meeting of the Liverpool branch of the National Amateur Gardeners' Association was held on Thursday at the Common Hall, Hackins-Hey, Captain F. W. FREEMAN in the chair. There were on exhibition in the hall the usual display of flowers, plants, &c., which were duly adjudicated on by three of the members, and marks awarded to the best exhibits. Mr. JOHN COWAN, of Garston Nurseries, delivered an interesting address on the subject of Orchids. Mr. COWAN had with him some beautiful specimens of *Dendrobium Phalæopsis*, which were greatly admired.

THE FRUIT AND POTATO SHOW AT EARL'S COURT.—The judges, having reconsidered the awards, gave E. D. SHUTTLEWORTH & Co. a Gold Medal, instead of a Silver Medal, as reported. W. W. JOHNSON & SON received a First-class Certificate for a new Potato, Boston Quantity and Quality; and a Silver Medal, instead of a Bronze Medal, as stated in the report.

THE PRINCES STREET GARDENS, EDINBURGH.—The proceedings in the arbitration between the Corporation of Edinburgh and the North British Railway

Company as to the price to be paid by the latter for the ground taken by them in Princes Street Gardens, as we learn from the *Scotsman*, October 6, were resumed recently in Dowell's Rooms, George Street. The oversman in the reference is Lord Shand; Mr. Dunlop, Westminster, is the arbiter for the Corporation; and Mr. James Davidson, Saughton Mains, acts as arbiter for the Railway Company. The parties were again represented by counsel as follows:—For the Corporation, Mr. Graham Murray, Q.C., M.P.; M. Comrie Thomson, and Mr. C. Scott Dickson, instructed by Messrs. Macandrew, Wright, & Murray, W.S.; for the Railway Company, the Solicitor-General (Mr. Asher, Q.C., M.P.), Mr. Ure, Mr. F. T. Cooper, and Mr. G. G. Grierson, instructed by Mr. James Watson, solicitor of the Company. The case for the Corporation, who claim a sum of £150,000, was continued, and the witnesses examined for them were Mr. Washington Browne, architect, Edinburgh, and Mr. Alexander Frew, C.E., Glasgow, both of whom spoke chiefly of feuing values; and also Mr. James Watt, of the firm of Messrs. Little & Ballantyne, nurserymen, Carlisle, and Mr. John Methven, of the firm of Methven & Sons, nurserymen, Edinburgh, who both spoke principally on the question of amenity and on the laying out of the ground. This closed the evidence for the Corporation, and Mr. Hamilton Beattie, architect, Edinburgh, was then examined as the first witness for the railway company. Mr. Beattie's examination had not concluded when the sitting closed at a quarter to five o'clock.

"COTTAGE GARDENING," published at a cost of one half-penny weekly, by Messrs. CASSELL & Co., and edited by M. W. ROBINSON, makes its *début* this week. It treats not only of the cottager's flower and vegetable garden, but of his bees and pigs, adding a page of miscellaneous advice on cookery, dress, and housekeeping. To further attract subscribers, prizes are offered for the best sketches or photos of cottage gardens.

LEMOINE'S HARDY GLADIOLI.—This beautiful race, originating from the cross-breeding of G. Lemoinei and G. Saundersianus, is known to many of our readers who had the opportunity of seeing them and of hearing what M. LEMOINE the younger had to say concerning them at one of the meetings of the Royal Horticultural Society. A coloured plate, representing some of the forms, is given in the *Revue de l'Horticulture Belge* for October.

"GARDENING" is the title of a new fortnightly periodical issued by the Gardening Company, Monon Building, Chicago (Editor, Mr. W. Falconer). The prospectus announces the publication as a "plain, practical paper, in plain language, gotten up with the view of aiding everyone who is interested in a garden, more especially the amateur." In the first number this programme is well carried out, the whole paper being full of information, attractively "gotten up" and illustrated.

AMERICAN PLANTS.—Under the title, "Contributions from the United States National Herbarium," various papers on systematic botany are issued, under the auspices of the Department of Agriculture (Division of Botany). The lists are of great value to working botanists. Collections illustrative of the floras of Cocos Island, the Galapagos Islands, and Patagonia, are enumerated, and a complete systematic and alphabetical index of all the flowering plants of North America published within the year, added. Some illustrations add to the value of the publication.

LILIUM SULPHUREUM.—This is the beautiful Lily lately exhibited by Messrs. Low. It resembles the Himalayan *L. Wallichianum*, but that has pure white flowers, more slender anthers, with bright yellow pollen, and does not produce bulbils in the axils of the upper leaves. The present plant has scattered linear leaves, drooping flowers 7 to 8 inches long, sulphur-yellow, tinged outside with claret-red. It is a native of Burma, and is described and figured by Mr. BAKER in the *Botanical Magazine*, sub-t. 7257.

MODERN FRUIT CULTURE.—Messrs. G. BUNYARD & Co., Maidstone, have reprinted in the form of a pamphlet various papers by themselves and others, and intended to convey information concerning fruit culture. It supplies just the kind of knowledge which amateurs want, and may be recommended as furnishing practical information without an excess of detail.

GOLDEN WEDDING.—On Wednesday, October 5, Mr. Alderman W. H. ROGERS, J.P., and Mrs. ROGERS, of Red Lodge Nursery, Southampton, celebrated their Golden Wedding. The congratulations and presents were numerous, and not the least appreciated by the recipients was a handsome present, consisting of an illuminated address by the employés.

"FERNS OF BRITISH INDIA."—A supplement to Colonel BEDDOME'S most useful *Handbook to the Ferns of British India* has just been published by THACKER, SPINK & Co., of Calcutta, and 87, Newgate Street, London. The original work was published in 1883, and this brings our knowledge up to the present time. The additions made have been principally in the Malay peninsula, where SCORTECHINI, KUNSLER, and others, who have worked under the auspices of Dr. KING, have discovered a good many new species, and added to the Indian flora many other Malayan types not known previously within Indian bounds. The work contains also a new working up of the true *Nephrodium*, the discrimination of which is very difficult. The pamphlet is the same size as the original work, and contains 110 pages, without any plates.

THE ANT-BEAR.—Mr. A. C. MACDONALD, in *Agricultural Journal*, Cape Colony, says:—It is a failing with the human race that, in the pursuit of "sport," they at times attack friends as well as foes. A case in point is the war which is being waged against that peculiar quadruped, the ant-bear, "aardvark." Anyone conversant with the habits and nature of this animal, knows that it is one of the few indigenous four-footed friends of the farmer of this colony. Its food is the ant, more especially the white ant, an insect which feeds on our crops and the succulent herbage of the field, and which does much greater damage than is generally supposed. Although the ant has numerous enemies, among which is reckoned the koran, a bird which, I am happy to say, is now being preserved on some farms solely for this purpose, yet none are so destructive to its welfare as the ant-bear. It is only when on the surface of the ground that the ant runs any danger from its winged foe, but above or below ground it is always within reach of the ant-bear. But it is not only as a destroyer of ants that the ant-bear is of value to the farmer. A large percentage of the seeds of our herbage after they have dropped off the plant on to the hard ground, lose their germinating power from being exposed day after day to the scorching rays of the sun. The ant-bear, as it goes scratching about for ants, covers a large number of seeds with loose earth, in which congenial bed they will retain their reproductive power for a long period, awaiting the moisture from the skies to shoot out and propagate their kind. And yet this animal, harmless in other respects, is being slowly but surely exterminated. For its skin, which is valued at about 15s., and also for its flesh, which resembles superior pork, it is sought after by the natives. With the white race "sport" is the inducement, this fun taking the form at times of forcing the poor brutes out of their holes by flooding with water, or drowning them in their holes and afterwards digging them out. The subject of the protection of the ant-bear has been brought forward for discussion by the Zwart Ruggens Farmers Association, and I hope to see other associations following the example.

PUBLICATIONS RECEIVED.—*Treatment of Fungus Diseases*. L. H. PAMMEL.—*Pollination of Flowers*. L. H. PAMMEL.—*Horticulturist's Rule Book*, 1892; 2nd edition. (Rural Publishing Co., New York.)

A TRAVELLER'S NOTES.

(Continued from p. 469.)

CALCUTTA BOTANIC GARDEN.—Starting again in the afternoon from Dr. King's bungalow, we directed our steps towards the north, Mr. Proudlock again kindly placing his time at my disposal. On our way we passed some tall Mahoganies, with stems like great Elms at home. Opposite the bungalow is a Nipa fruticans, with long stiff leaves, which, when split, are used for thatching houses. Another winding lake, with numerous arms, all of which cannot be seen from any one point, rendering the effect very pretty, is soon reached in this part of the garden. There seems no lack of water. Great bushes of Bauhinias, covering many square yards, are near, and a magnificent Terminalia Catappa, over 100 feet high, with pretty red-tinted foliage, rises straight and tall on the edge of the grass; and a row of Mahogany, Swietenia Mahogani, with stems $4\frac{1}{2}$ to 5 feet through, is a little beyond. Sterculia alata is a fine tree, tall pyramidal head, on a smooth straight stem; there are some near the great Banyan, situated in this end of the garden.

The great Banyan, figured in *Gardeners' Chronicle*, Oct. 1, p. 469, is big—a needless remark; its main stem is 48 feet in circumference, and it is 106 years old. In 1886 it had 232 aerial roots, many big enough to form the trunk of a fine tree. Now there are, of course, many more. The space covered by this gigantic tree is about 70 yards through. On one side a huge branch, which must have been some 40 yards long, was whipped clean out by a cyclone, how I cannot imagine, and many others are supported, some by brickwork. The tree is in good condition, and apparently growing as freely as ever. As there is little vegetation in its immediate neighbourhood, there seems to be no reason why it should not go on for a long time. Philodendrons, Anthuriums, and other creepers, grow over its main stem, and along its chief arms.

I am told much alteration has been made in this part of the garden, it is now covered with grass, gently undulating, and with fine roads; whereas previously it was quite flat, and more or less overgrown. A portion near is quite English in its aspect, being planted with Dalbergias, and such like. Were it not for the stems of a few tall Phoenix, one might be looking at an English landscape from the distance. Before reaching another fine avenue of Polyalthia longifolia, nice regular pyramidal specimens, some 30 feet high, Mr. Proudlock pointed me out a bush of Lagerstromia tomentosa. He tells me its orange-red flowers are a magnificent sight in the rains.

On the other side of the avenue we made a *détour* to look at a Cannon Ball tree, a specimen of which was recently figured in the *Gardeners' Chronicle*. It was not in fruit, but I saw some flower-buds, borne on the main trunk—a curious sight, as it was 2½ feet in diameter—the old flowering-stalks, some of considerable length, still remain. Its name is Couroupita guianensis—a native of the West Indies.

Opposite another fine Terminalia is the Brownea before referred to. They are not yet considered to be in flower—it is still too cold (though as I write the thermometer is 72° in my cool room), but I saw many hundred heads of blooms, chiefly coccinea and other varieties, but none of grandiceps. They were, however, not large, and evidently not fully developed. This avenue, or rather tunnel, about 100 yards long, must be a magnificent sight in the season. There is but little perceptible cessation of growth all the year round with these plants.

The pond or lake with its winding banks is again touched at this point—it has three islands on its surface—clothed with rich vegetation, and in the

distance a view is caught of the long Grevillea robusta avenue—some 40 to 50 feet high.

The Palm-house—a great octagon, before referred to, is now reached. Rarely have I seen a prettier sight than the interior of this place—winding walks, and low, rockery-edged beds. All kinds of what we call stove plants, Palms, and Ferns, most tastefully arranged, grow with extraordinary freedom—the great point being to keep the plants from overcrowding and to thin sufficiently. A pretty creeper up one of the pillars supporting the roof is worth naming—Faradaya papuana—with white, powerfully-scented flowers, not unlike a Honeysuckle. On leaving the house and looking north, one sees a great Parkia biglandulosa, a tall tree, with small pinnate foliage, and a Sterculia ornata, a fine sight, completely covered with creamy white racemes from top to bottom. Passing a specimen of the Log-wood tree, the Little Banyan is reached—large enough in all conscience—it is nicely draped with Philodendron and other creepers. The soil round the base of the main stem is hidden by Tradescantia.

Close here is a model plantation of the best varieties of Mangos, and in the distance I caught sight of tall pillars of Thunbergia—blue and white ones—some 70 feet high, draping old Casuarina stems—a fine sight though not in flower.

The flower garden is now soon reached, on the right of which is another large, though low house, flanked on either side by two tall Araucaria Cunninghamii. Beds of various shapes, filled with what annuals will do, composes this garden. I was too early to see any results—particularly as the coldest season is now over, and it daily becomes warmer—but Mr. P. tells me the results are good.

Within the house are all kinds of plants, which, by-the-by, do equally well outside—Pothos, Ferns, Alocasias, Palms, Anthuriums being amongst the number. I expect these houses are most useful in the hot weather as shade, especially to Ferns.

Outside the house in front of a fine clump of Crotons is a big bush of Ixora Dull—fine broad heads of flower are now being borne; and a little beyond is a fine group of Conifers, Cupressus sempervirens, Biota orientalis, Podocarpus chinensis, all three species of Araucaria already named, Cupressus torulosa, and some Pinus longifolia, with leaves 14 inches long, of a rich green, glistening in the sun—a very pretty Pine, and more luxuriant here, though not so tall, than I think I have seen it anywhere else.

A big bed of Euphorbia heterophylla close here, attracts notice, the verticil of biggish bracts at the end of each shoot is curiously coloured. One half of the bract is bright vermilion, the other being bright green; there is no intermediate shade, the line of demarcation between the two colours is sharp.

Near the rose-garden, not far from this house, is a fine group of Palms, but the Roses are poor; we can expect little else here. I was surprised to catch sight of a Magnolia grandiflora, Exmouth variety, in fine condition. It is shaded by a jungle of Browneas and an Amherstia, a curious mixture.

Another long house, in which are the Nepenthes in fair condition, and some Orchids hanging from the roof, as well as some on the brick beds, now comes into view. Some of the Orchids are good—Vanda Roxburghii, Cypripedium Spicerianum, Stanhopea eburnea, Calanthes, and several Phalaenopsis, being in flower. On the rockery near the doors are Ferns and many low-growing stove plants. A curious plant, a native of the Andaman Isles, was pointed out to me by Mr. Proudlock—Hydnophytum andamanense. It is grown as a pot-plant, and has a curious, thickened, short, round stem, and thread-like foliage.

The nursery is a little beyond, with all kinds of small plants, and several glasshouses for use in the cold season. Cattleyas, Lælias, and Phalaenopsis, are found to require this protection in the cool months, but the two former are nevertheless not good; it is also too wet for them in the rains. These glasshouses are not heated, or Cattleyas and Lælias might perhaps do better.

I noticed some magnificent plants of Anæctochilus Dawsonianus, as well as some Vanda teres, grown on teak sticks, in fine condition; they receive partial shade.

There is a fine house of Dendrobiums, certainly the Orchid genus best grown in India. All kinds are represented; densiflorum, albo-sanguineum, Dalhousianum, and moschatum, being amongst the best. Cymbidiums were also good, and Phaius Wallichii especially so. *James H. Veitch.*

SCOTLAND.

MR. JOHN FORBES' NURSERY, HAWICK, N.B.

I WAS desirous of seeing some autumn-flowering plants at their best, and with that intent, visited the above nursery on September 12. The first objects that attracted my attention were the large beds of East Lothian Stocks, white, crimson, scarlet, and purple, and white and crimson Wallflower-leaved. The strain was a good one, for the percentage of doubles to singles was very large. Carnations are extensively grown, and among the many beds (of which the old plants were layered) some fine varieties were remarked. Mr. Forbes pointed out some beds which were much stronger than the others, having more grass, more flower-spikes, and looking better in every way; these beds were planted in autumn, and clearly showed the advantages of autumn planting. Several large beds of Pentstemons were noticed, which looked beautiful, the masses of flower-spikes, and the individual blooms being very fine. Large beds of Antirrhinums were masses of bloom, and the flowers would be hard to beat for size and colouring. There were two beds of these plants of a variety called Crimson Bedder, and that is certainly well-named; it is of dwarf habit, and flowers profusely. Another of much the same habit is named White Bedder: it is equally good.

As is well known, Mr. Forbes grows Pansies to perfection, but it was rather late for these; still, there was a good number of blooms expanded. The Phloxes were represented by the best varieties, and some fine heads of bloom were observed; very dwarf late-flowering varieties were conspicuous for their numbers. Among the herbaceous plants were many good things, and of which there is a large collection.

In the glass department I will only mention a few of the good plants that I had time to note. One long span-roofed house was full of single and double-flowered tuberous Begonias, and although these were past their best, they formed still a fine display. A fine strain of excellent Cockscombs, and another of the feathered Cockscomb (Celosia pyramidalis) grown for seed-saving purposes. A number of Hydrangea paniculata were in flower. It is a fine autumn decorative plant for the glasshouse, but I doubt if it would withstand the cold of an ordinary Scotch winter. Table plants, and those for room decoration, seem to be in great demand.

A large span-roofed pit was filled with East Lothian Stocks in pots. The plants were carrying a splendid crop of seed, which was almost ready to gather. *J. R.*

DUTHIE PARK FLORAL FÊTE.

The accounts of the above—held in Aberdeen on Aug. 5 and 6 last, under the auspices of those directors of the Royal Horticultural Society of Aberdeen who did not approve of holding military tournaments in connection with flower shows—have now been made up. The entire takings amounted to £501, and the expenditure to £487, leaving a balance of £114. Of this sum, £100 have been sent as a donation to the Aberdeen Sick Children's Hospital, the remaining £14 being reserved for any incidental expenses which may occur. The committee have resolved to present one of the handsome Medals struck in commemoration of the fête to Mr. McBaio, C.A., Aberdeen, for the admirable manner in which he carried out the secretarial duties; to Mr. Harper, keeper, Duthie Park, for the trouble he took in connection with the fête; and one to the bandmaster of the Royal Scots Fusiliers. The committee presented a handsome copy of the Medal in gold to the Chairman of the committee, bearing the following inscription:—"Awarded to Baillie Lyon by the Duthie Park Floral Fête Committee, 5th and 6th August, 1892."

In connection with the recent floral gala and military tournament of the Royal Horticultural Society of Aberdeen, the directors have resolved to present Colonel Sir Arthur Grant, Bart., of Monymusk, with an illuminated address and a handsomely-bound album of photographic views, depicting the

various phases of the tournament, as a slight recognition of the invaluable services rendered by him in connection therewith. Albums will also be presented to Major Wood, R.E., and Captain Forbes, R.F., who rendered yeoman service in the carrying out of the arrangements.

THE BULB GARDEN.

SOME NEW FORMS OF COLCHICUM AUTUMNALE.

THE handsomest of these free-blooming hardy bulbs is *C. Sibthorpii*, figured on plate 7181 of the 117th volume of the *Botanical Magazine*, and which is a native of the mountains of Greece and Macedonia. It was introduced into cultivation by Herr Max Leichtlin, of Baden-Baden, who sent bulbs to Kew in 1890, where it bloomed in the autumn of 1891, and it was distributed to the public for the first time from the same source at the commencement of this autumn, and it is now in full bloom in my garden. It is, however, evidently a very variable plant, as of the five bulbs sent me from two different nurserymen, the flowers of no two are exactly similar, some having thin narrow-petalled flowers resembling a dark-red form of *C. Parkinsoni* or *tesselatum*, while others are much lighter in colour, with almost white centres, and finely-cupped flowers with well-rounded petals; these latter are, of course, much the more beautiful. This *Colchicum* was figured by Sibthorp in his fine work, *Flora Græca*, under the name of *C. latifolium*; but this name is now determined to belong to the variety known as *C. Byzantinum*, which with us is the earliest to bloom of the whole genus.

Another fine deep-coloured and early-blooming *Colchicum* has come to me under the name of *C. Bornmülleri*, but this only seems to be a fine form of *C. speciosum*. Another with deep-rose coloured and perfectly-cupped flowers, which came to me under the name of *C. speciosum maximum*, seems to me in no wise to merit the latter appellation; as though very beautiful, it is by no means a specially large flower, and seems to me to be identical in every way with a form I have grown for some years under the name of *C. speciosum persicum*. The last I have to mention is *Colchicum Decaisnei*, which was first described by the French botanist, Boissier, in his *Flora Orientalis*, vol. v., part 1, p. 157; it seems, however, to be almost unknown in this country, as on making enquiries about it at Kew, I find there is no specimen of it in the Herbarium. It was, I believe, first introduced into cultivation by Messrs. Dammann, a German firm, who grow many rare bulbs in the vicinity of Naples, and who, not knowing what it was, sent it to the late Dr. Regel, of St. Petersburg, for identification, who pronounced it to be *C. Decaisnei* of Boissier. From this firm I received my bulbs, which are now in full bloom in a pot in my greenhouse, and are very pretty, though of rather small size and thin texture of petal. The flowers are of a delicate shade of rosy-lavender, and about $2\frac{1}{2}$ to 3 inches high; they are abundantly produced, each bulb yielding from twelve to fifteen. The flowers are said to be sweet-scented, but this I cannot perceive. This variety is closely allied to *C. latum*, but is, in my opinion, well worth cultivation. *W. E. Gumbleton.* (See p. 458.)

HOME CORRESPONDENCE.

THE WHITE WATSONIA.—A communication respecting this bulb appeared in your paper under date August 20, 1892, signed "P. MacOwan, Cape Town." Your correspondent says, amongst other things, "that he does not suppose I had any intention of misleading the readers of my 'note.'" I certainly had no intention of "misleading" or leading any readers, for the reason that I never wrote, or in any way inspired the note referred to, and saw it for the first time in your journal. He twits me with my "want of information about the plant's origin." My information, on that point, however, is superior to his own. I know precisely the date when two bulbs of it were

sent to my predecessor. I further know from the finder himself the name of the farm, where he found it; and still further, I have at all times in conversation, and otherwise, on the subject given all the information I possessed to any one interested. *John T. Butters, Superintendent of Parks, Port Elizabeth.*

CARNATION MARGUERITE.—In the *Gardeners' Chronicle* for September 24 last we have read an article under the heading "Florists' Flowers," and signed J. Sheppard, in which the writer says that it would be interesting to know how the *Carnation Marguerite* originated. We have the pleasure to inform him that this plant was found by us in Sicily, and that it has been cultivated by us since the year 1882. *Dammann & Co., San Giovanni a Teduccio, Italy.*

TOMATOS AT BRIDGE OF ALLAN.—In these times, when Tomatos are grown so extensively and to such perfection, it is difficult to find any particular variety which shows a decided superiority over others. A notable example of success in the culture of the Tomato, and great superiority in the variety grown, came under the writer's observation at Cornton, near Bridge of Allan, during the past summer. Here, Mr. McGregor, who for some years was manager of extensive establishments at Waltham and in Guernsey, has recently started market gardening in general, and Tomato-growing in particular, and bids fair to maintain in the north the high reputation he won in the sunnier south. The sort grown is one of his own selection, and is remarkable for its smoothness, free-setting qualities, and the uniformity of its clusters. From 12 to 16 lb. of fine medium-sized fruit was borne on single stems, and a desirable characteristic of the variety is the simultaneous ripening of all the fruits on a cluster, thus enabling the grower to dispose of each *en masse*—a style which is becoming very popular in the market when the fruit is highly-coloured and shapely. Connoisseurs, I may add, pronounce the flavour excellent. Mr. McGregor believes in keeping the plants somewhat dry at the root until the first bunches are set, afterwards applying heavy doses of liquid manure, which in his case is sewage, and he attributes a good deal of his success to this kind of treatment. But be that as it may, the appearance of these Tomato-houses when at their best, with no trace of disease on the plants, was wonderful, and augurs well for the success and further development of this business concern. *J. M. G.*

STEAM VERSUS HOT WATER.—Before going to America in 1889 I had often heard that Messrs. Peter Henderson & Co., of New York, had most of their hothouses heated by steam, one of the first enquiries that I made at their nursery was about this subject, and I was informed that it did not answer and hot-water had been substituted for it. I am not sure what reason was assigned for the change, but it was undoubtedly a good one, or the firm would not have gone to such great expense as the change demands. I am in favour of steam-heating as practised in the American railway-cars, and wish our English companies would copy it, for there is no doubt it answers for that purpose and goes a long way towards making a railway journey comfortable in winter, but for hothouses I shall still rely upon hot-water which is perfectly efficient if plenty of boiler power is given and the apparatus is managed in a proper way, although it is quite possible steam might prove to be the cheaper in some few instances where it could be got from mills close at hand. *W. H. Divers, Ketton Hall Gardens, Stamford.*

WELL-COLOURED BLACK HAMBURGH GRAPES.—It was noticed the other day in "looking round" the gardens at Trafalgar Park, that the Black Hamburgh Grape in the two houses devoted to its culture was splendidly coloured, and carrying a good bloom, the bunches being of medium size and very compact. I have long been of opinion that Grapes colour much better in high situations than in low ones, and the fine colour of those at Trafalgar Park strengthens my conviction on this point very much indeed, as I know of no other garden that is situated at such a high altitude as Trafalgar Park. Mr. Fulford is to be complimented on the general good condition of the gardens and grounds under his charge. *H. W. W.*

A NOTABLE ELM TREE.—Within a few yards of the chapel at Trafalgar Park, Wilts, there stands an Elm tree of great size, which is however more remarkable for its girth of trunk than for its spread of branches, which is nearly 24 feet, from the ground up to a height of 6 feet, where it begins to branch. The tree is about 140 feet high, and is in fine condition. *H.*

VEITCH'S PRODIGIOUS POTATO.—This is one of the heaviest cropping varieties in cultivation, and a main crop variety of the highest quality, and remarkably free from disease. In 1891, the Rev. F. B. Dickenson, Ottery St. Mary, Devon, harvested a crop of this Potato yielding 105 lb. to each pound of seed planted. The Bishop of London's head gardener (Mr. A. J. Ballhatchet), raised 90 lb. from three tubers of seed size; and this year, Major Carew, of Elmsleigh, Exmouth, harvested 71 lb. of Potatos, all sound and of good size, from one tuber; while his neighbour (Frederic Morant, Esq.), of Glenholme, Exmouth, raised 97 lb. from 2 lb. of seed planted. *Robert Veitch & Son, Queen's Seedsman, Exeter.* [Veitch's Prodigious Potato was shown by the firm of R. Veitch & Son at the recent show at Earl's Court, where we had the opportunity of seeing a sample of it. It is a heavy, large oblong white tuber with rather deep eyes, like many American varieties, from which this one is derived, but this but little detracts from its value as a food producer. *Ed.*]

TREES NEWLY PLANTED.—In "D. T. F.'s" comment on my article in your last volume, p. 46, on cutting back newly-planted fruit trees, he seems to have entirely missed the main point for which I was contending. I thought I had put the case and its consequences clearly enough to most minds, but to him the picture is nothing but shadow. I need not here go into much repetition, but would like to remind your readers that my council with regard to cutting back referred particularly to newly-planted fruit trees; but "D. T. F.," in taking up the cudgels in defence of his newly-adopted theory of planting—the let alone—has endeavoured to make me an advocate for planting fruit trees for faggot-wood, and going back to the ancient "lashings and slashings" of not so long ago. He may see that I am no advocate for the first of these methods, he has only to turn to one of your issues for last February, wherein I stated that throughout the country a great many fruit trees would be found which would have more value as fire-wood than as fruit trees; and as for the latter, I am quite as much opposed to the lashing and slashing of established fruit trees as himself. May I ask "D. T. F.," how many years ago it is since he gave up the "ancient lashings and slashings?" and especially how many since he gave up heading-back his newly-planted fruit trees? Did ever "D. T. F." try planting Raspberry canes without cutting back, and note the extent of successional growth made concurrently with the crop of fruit the canes may carry the following season? Or did he ever try raising, say two Cob-nut bushes of one variety, and both weakly to start with, by "slashing" one down to the ground and leaving the other alone, and then noting which was the stronger and better furnished bush, at maturity—and to go even further, which arrived at maturity first? If not, let him try some such simple experiments as these—the results will be edifying even to him. Let me assure "D. T. F." that the time was long ago when I first made myself familiar with the influence that laying-in plants and trees by the heels had on the formation of fresh root fibres; but had I been he, and noticed such a common fact, I would, for the benefit of less enlightened readers, have endeavoured to give my reasons for this abnormal activity and I would have also said that time when done as a particular bearing and position more so upon the roots of those trees and plants susceptible to this influence; neither would I have neglected to add that there are a great many trees, shrubs, and plants, the roots of which, disturb them how you like, would not be thus influenced at all. "D. T. F." speaks of the amount of skill and capital invested in developing baby fruit trees, and wonders why they should not be allowed to enter upon their life-long business at once of bearing fruit. I suppose because people do not want them to remain babies, as they assuredly would do if allowed to bear at once, and as much as they would; or, if "D. T. F.'s" axiom of like produces like, these baby trees would only bear baby fruit. Depend upon it, most people nowadays, although they have to buy baby fruit trees, do not wish them to remain pigmies for all time, but rather endeavour to grow them into fair shape and size; they want dwarf trees, but they also want to count the crop of such by the bushel, instead of by the dozen. To hurry such trees into fair shape and size—or, in other words, into a remunerative bearing condition—cut them back at time of planting, less or more, according to the time this operation takes place, and have no fear for the results. There is no doubt at all, as "D. T. F." remarks, that the modern methods, restricted as they are to stocks and double grafting, have hastened and heightened fertility in a wonderful degree; but even

with these dwarf early-fruited trees, there is no reason why they should not be allowed to establish themselves, and fairly fill the spaces allotted them; instead of making and retaining them as pigmies, these ought to be retained for pots. "D. T. F." may talk as he likes of faggot-wood, but the disposition to grow this in young trees—the class he means, I assume—is very easily checkmated in the way he himself mentions, or as many of our best fruit-growers prefer by root-pruning, or what is equally good in the case of small-sized trees, by lifting them. Does he therefore imagine that any sane fruit-grower who knew his business would allow his young trees to present the picture—not a whit overdrawn—I gave of those on the let-alone system in your issue of June 4, p. 730. I think it almost needless here to point out, even to the veriest tyro in fruit-growing, the ultimate difference, commercially, between these two types of fruit trees. Many amateurs are far ahead of "D. T. F." in regard to this matter of heading back newly-planted fruit trees, and it was, therefore, a pleasure to me to meet with several who had tried the let-alone system, but had gone back to cutting-in, and this, too, in a county where the advice was invariably tendered to "let them alone for the first twelve months," in order to enable, as they were told, "the trees quicker to establish themselves by inducing greater root activity." While lecturing last winter in Kent, I visited many of the parochial clergymen, nearly all of whom are ardent horticulturists, and, as such, many stand out head and shoulders above their professional brethren. On these occasions a walk round the garden was of all things the most natural to propose and be accepted, and while in one of these gardens I noticed a fine assortment of both Apples and Pears had been recently planted (this neighbourhood being famed for its fine Pears), although a great many older trees abounded in the place. I noticed also that every one of these newly-planted trees had been pretty freely headed back, and on my remarking to the owner that I was pleased to see he had taken the precaution to do this, "Ah!" he replied, "that is the result of experience. I soon found out that if I left them to bear and grow as they liked from the first, I should never get a tree at all." And really this is the whole thing in a nutshell. This heading back does pull the roots abreast of the tops in measure, but not in time, and it certainly does improve and intensify the fertility of the top ultimately. "D. T. F." is alive to the fact that cutting back trees establishes them quickly, else how would they grow faggot wood? By this means, then, let our trees be established; it is impossible for them otherwise to carry on the dual work of bearing fruit and making good growth at one and the same time. I have hitherto confined my remarks with regard to this question of heading back to young fruit trees, but what would "D. T. F." think of moving large deciduous trees of, say twenty years' growth, and 25 to 30 feet high, with no ball and the roots horribly mutilated, and leaving severely alone, and this too in the month of February? Will he maintain that success would have attended his efforts? But what would he say to fifty trees of over thirty-five years' growth, 40 to 50 feet high, and from 3½ to 4½ feet bole circumference, being moved a distance of 2 miles with most complete success in the first week in March, and this too without any previous preparation whatever? An oft quoted dictum of "D. T. F.'s" is "nothing succeeds like success," but I think he will admit this was a success. Had these trees been left alone (their branches intact), every one of them, it is almost needless to say, would have miserably failed. The first bursts of April sunshine would have forced into momentary growth the thousands of buds to draw, like so many leeches, upon the life-blood of the branch tissues, while what little remained of the roots still lying inert, ill provided to supply even a moderate demand on their resources. Although his criticisms are welcome, "D. T. F." should, I think, have made himself master of the main points for which I was contending in the article in question, before endeavouring a reply in the way that he has. Whether I am qualified to pronounce *ex cathedra* or otherwise on the precedence of growth as between root and top, I certainly do know what evil effects non-pruned tops have upon the establishment and permanent well-doing of newly-planted fruit trees. Your correspondent had better go burrowing now, and try to unearth theories more tenable, and in the shape of reason for his adhesion to the cult of leave-them-alone, and if he will only give this matter for the future a little closer attention than he has yet done, he will be able, doubtless, to find a reflex,

with a good deal more substance than shadow in it. *Pomum.*

APPLES IN STAFFORDSHIRE, ETC.—In a season like the present, when fruit is scarce, and anything approaching a good crop is rarely to be met with, it was an agreeable surprise to me recently to find some trees cropping well at Ingestre Hall, Stafford, the seat of the Earl of Shrewsbury. The fruit was of fair size, and beautifully clean-grown, the varieties being Lord Suffield, Adams' Pearmain, Cox's Orange Pippin, Devonshire Quarrenden, Duchess of Oldenburg, Golden Russet, Lemon Pippin, Lord Lennox, Red Astrachan, Sturmer Pippin, Keswick Codling, Wykin Pippin, Cox's Pomona, Grenadier, Worcester Pearmain, Mère de Ménage, Warner's King, Golden Noble, and Bramley's Seedling. The trees were in capital health, and free from blight and aphid. The grounds and surroundings of this splendid place were in capital order. I also noticed a capital lot of specimen Chrysanthemums in vigorous health. These were being placed in their winter quarters. The hot-houses were in good order, and the specimens highly cultivated. There were a capital house of late Grapes and a good crop of late Melons. Every department bore traces of the careful supervision of the head gardener, Mr. Gilman. *Wm. M. Baillie, Flitwick Nursery, Beds.*

CHRYSANTHEMUM AND PELARGONIUM GRAFTING.—I noticed a curious and successful experiment in this direction recently at Boston House, Brentford (Colonel Clitheroe's), where the gardener, Mr. C. Jeffries, has grafted eight sorts of Pompons on the well-known variety Mrs. George Rundle, arranging the grafts so as to give some little arrangement as to proper balance of colour at the flowering period, which one will watch with some interest. By grafting the tricolor varieties on the green-leaved varieties, Mr. Jeffries finds that he gets a much quicker and sturdier growth, the tricolors, as a rule, being weedy and slow growing. A fine batch, observed recently, sufficiently established the truth of this statement. The plants, which formed capital little standards, were destined to form specimens for vases, and similar decorative purposes, and exhibited a clean growth, the foliage being more brightly coloured than is usually seen in plants cultivated under glass. *B.* [Pelargonium grafting to form standards for the greenhouse or flower garden, has been practised for a number of years. For stocks on which to graft strong-growing varieties, or better, seedlings which are usually great growers, are employed. Seedlings may be got up to a height of 3 or 4 feet by training the main stem and stopping, not removing the side shoots. *Ed.*]

SOCIETIES.

NATIONAL CHRYSANTHEMUM.

OCTOBER 12.—The early autumn exhibition, and the second of the season, was opened on Wednesday, in the Royal Aquarium, Westminster, and although the entries were not numerous, some very good blooms were exhibited, and also some striking seedlings and sports.

The principal prize was for a group of Chrysanthemums arranged in a space not exceeding 72 square feet, quality primarily, and general effect, to be the leading features. Messrs. Reid & Bornemann, nurserymen, Sydenham, were 1st, with a creditable group for the season, containing some very fine blooms, especially of the Japanese and reflexed sections; some Pompons, also, were very well flowered. The 2nd place was taken by Mr. Norman Davis, nurseryman, Camberwell. Both of these groups would have appeared to much better advantage had the pots at the exterior been bid with some furnishing.

Mr. H. Neary, gr. to Rev. R. W. Powell, Holy Innocent's Vicarage, Hornsey, N., was 1st for six plants of Chrysanthemums (open), with two plants each of Madame C. Desgranges, George Wermig, and Mrs. Berrell, very even flowered and dwarf plants, containing some seventy or eighty flowers on each plant. The same exhibitor was awarded 1st prize for twelve plants, any varieties. This was not so good a collection as the six, and many of the flowers, especially on Madame C. Desgranges, were past their best. Mr. W. Howe, gr. to H. Tate, Esq., Streatham Common, was 2nd, who showed twelve tall standard plants, each bearing two blooms.

In the classes for cut blooms, some of the exhibits

were exceedingly fine. The 1st prize for twenty-four blooms, in eighteen varieties of Japanese, which was secured by Mr. W. Higgs, gr. to T. B. Hankey, Esq., Fetcham Park, Leatherhead, being awarded to a really beautiful collection. The varieties were Condor, W. H. Lincoln, Violet Rose, F. A. Davis, Mons. Bernard, Madame Lacroix, Avalanche, E. Molyneux, Gloire de Rocher, Mrs. Nisbet, Boule d'Or, W. Tickner, Louis Boehmer, Val d'Andorre, Puritan, Sunflower, Miss Anna Hartshorn, Excelsior, Condor, and Irving Clarke; the 2nd position was taken by Mr. C. Cox, gr. to J. Trotter, Esq., Brickendon Grange, Hertford, who had fine blooms of Avalanche, C. Cox, and Boule d'Or; 3rd, Mr. C. Ritchings, gr. to Dr. Frankland, The Yews, Reigate Hill.

For twelve blooms, distinct (open), Mr. F. Rowbottom, gr. to H. R. Williams, Esq., The Priory, Hornsey, with W. H. Lincoln, Marquis de Paris, Mr. J. S. Fogg, Stanstead White, Edwin Molyneux (good), Bouquet de Dame, William Tucker, Coronet, (very nice), Mons. Jules Hubert, Mrs. Falconer Jameson, Mons. Bernard, and Amos Perry. Mr. James Agate, East Street, Havant, Hants, was 2nd, who included good blooms of Lillian Cope and Mrs. Irving Clarke. The 3rd place was secured by Mr. C. Cox, gr. to J. Trotter, Esq., Brickendon Grange, Hertford.

In the class for twelve incurved blooms, in not less than six varieties (open), and for six blooms of incurved distinct, the only exhibitor was Mr. W. Wells, Earlswood Nurseries, Redhill, Surrey. The specimens were only fairly good, but it is more difficult to obtain flowers of this section at an early date than those of the other classes.

Mr. Norman Davis made the only appearance in the class for twelve varieties of Pompons, in bunches of threes, and also secured the 2nd place for six varieties, the 1st prize in this latter going to Mr. E. Tickner, gr. to John Watney, Esq., Shermanbury House, Reigate, with very good Middle. Elise Jordan, Black Douglas, Souvenir de Jersey, Curiosity, La Vogue, and Toussaint Maurisot.

In the section for single-handed gardeners only, Mr. E. Tickner was 1st for twelve blooms of Japanese (distinct), and staged Jean Delaux, Fanny Bourcharlat, Hamlet, Mr. Garnar, Louis Boehmer, Madame Lacroix, Mons. Bernard, Eynesford White, Val d'Andorre, Sunflower, Edwin Molyneux, and W. H. Lincoln. This same exhibitor was 1st also for six varieties, being followed in this class by Mr. T. L. Turk, gr. to T. Boney, Esq., Cholmeley Lodge, Highgate. Miss Debenham, St. Peter's, St. Albans, obtained a 2nd prize for twelve bunches of Pompons, in the same section.

In the balcony were some tables upon which were exhibited as beautiful display as the florists are capable of. The competitions were for the best table of bouquets, wreaths, sprays, &c., illustrating the decorative value of Chrysanthemums, each exhibitor having the use of a table of 54 superficial feet. The 1st prize went to Messrs. Perkins & Sons, nurserymen, Coventry; the 2nd to Mr. R. Chard, Stoke Newington; and the 3rd to Mr. Henry O. Garford, florist, also of Stoke Newington; and Mr. F. W. Seale, Vine Nursery, Sevenoaks, was Highly Commended.

For three vases or epergnes, suitable for a dinner-table, Mr. W. Seale was 1st, Mr. J. R. Chard 2nd, and Mrs. Walter Mole, 22, High Street, Hemel Hempstead, 3rd.

Miscellaneous—Mr. W. J. Godfrey, Exmouth, Devon, showed some first-class blooms of new seedling Chrysanthemums. Beauty of Exmouth, a large white Japanese, was awarded a First-class Certificate. Mr. Robert Owen, Castle Hill Nursery, Maidenhead, also had a lot of seedlings of some merit, particularly a seedling from E. Molyneux, which the committee have requested to be shown to them again.

Mr. H. J. Jones, Rycroft Nursery, Lewisham, obtained First-class Certificates for Mrs. Hubback, a large rose-coloured Japanese, and for Felix Cassagneux, a bronze-yellow Japanese. Mr. Fowler, an amateur from Taunton, brought some superb blooms of Felix Cassagneux, but these did not arrive in time for the committee to see them; also some capital blooms of Mr. J. S. Fogg and Mr. J. Woodstock.

Messrs. Pitcher & Manda, Hextable, Swanley, had a collection of fine cut blooms of all sections of Chrysanthemums, and some Asters, &c. (Silver Medal).

Messrs. Reid & Bornemann, some trusses of zonal Pelargoniums, for which a Vote of Thanks was awarded.

Mr. Norman Davis, Camberwell, had cut flowers of Pompon Chrysanthemums, a large collection of Asters, &c. (Silver Medal).

Messrs. Reid & Bornemann exhibited many seedling Chrysanthemums, one of which, a very pretty Pompon, the committee desired to see as a plant, the name of which was Rosie Tanoko.

Mr. H. J. Jones, Rycroft Nursery, furnished a table with some good blooms of Chrysanthemums, arranged with Ferns, Palms, &c. (Silver Medal). Mr. W. Wells, of Earlswood Nursery, showed a large number of cut blooms of Chrysanthemums, including a beautiful white sport from Vivian Morrel, which the committee are to see again when better developed (Silver Medal). Messrs. Seale, Sevenoaks, had a very fine collection of Dahlia blooms (Silver-gilt Medal). Messrs. Cannell & Son, obtained a Bronze Medal for another collection of Dahlia blooms. Messrs. Joo. Laing & Sons, Forest Hill, staged a very pretty group of Begonias, Ferns, &c., and obtained a Silver-gilt Medal. This same firm also exhibited a very large collection of Apples and Potatoes, similar to those seen at Earl's Court last week (Silver Gilt Medal).

Messrs. J. Cheal & Sons, Crawley, had another excellent collection of Apples, and a few Pears (Silver Gilt Medal).

There was a very fine display of vegetables in competition for prizes that had been offered by Messrs. Sutton, of Reading, for Celery, Beet, Parsnips, Carrots, Leeks, Onions, Tomatoes, and Cauliflowers.

Floral Committee.

As is usual on these occasions, a meeting of the Floral Committee took place, when a number of new flowers were submitted, and the following awards were made:—A First-class Certificate of Merit was awarded to Japanese Beauty of Exmouth, a seedling from Avalanche, pure white, with lemon centre, a large, bold flower, of great promise, from Mr. W. J. Godfrey, nurseryman, Exmouth. Mr. Godfrey had Duchess of Devonshire, pale pink, with silvery reverse, which the committee wished to see again. Mr. W. Wills, nurseryman, Earlswood, had a white sport from Vivian Morel, which the committee wished to see again. Mr. Wills also had a primrose sport from Mdlle. B. Peigny, and La Cherire, a deep yellow variety of the Sunflower type.

Messrs. Pitcher & Manda, nurserymen, Swanley, had Japanese Coral Queen of a very distinct hue of coral and orange; W. A. Manda, a bright yellow flower of the M. A. Haggas type; Mr. E. Shea, a pale yellow sport from La Croix; Mrs. Jewell, a yellow Japanese; Zanzibar, a reflexed Japanese of a deep yellow colour; and Ruby King, very like President Hyde.

Mr. C. Griffin, Coombe Bank, Kingston, sent Mrs. R. Darby, a large deep pink single Japanese. Mr. H. J. Jones, nurseryman, Lewisham, had Japanese Amos Perry, a very fine yellow variety in the way of Coronet, but considerably superior; Felix Cassagneaux, gold and orange—a fine, reflexed October Japanese; Madame Eugène Klein, a very pretty blush-coloured variety, of great promise; and Japanese Mrs. Ironside, in the way of E. Molyneux, but of a different colour.

From Elstree House Gardens, Mr. E. Beckett sent Japanese Mrs. A. G. Habback of the type of E. Molyneux, carmine-amaranth, with silvery reverse, extra fine; awarded a First-class Certificate of Merit.

Mr. Robert Owen, nurseryman, Maidenhead, had Japanese Mrs. Myers, white, with lemon centre; Nathan Molyneux, like E. Molyneux, but with silvery and pink reverse; and October Yellow, very fine in colour.

Messrs. Reid & Bornemann had Hybrid Pompon Rosie Tauche, orange, edged with chestnut, a very pleasing variety, which the committee wished to see again. Some other flowers were staged, but some the committee will probably see again on a future occasion.

Obituary.

MR. ROBERT BULLEN.—We greatly regret to have to record the sudden death, on the 5th inst., of Mr. Bullen, the Curator of the Botanic Garden, Glasgow. He had been in his usual health till his sudden seizure. He was recently at the Earl's Court Exhibition, and attended a meeting of the Town Council of Glasgow only the day before his death. Previous to his undertaking the Curatorship at Glasgow, some twenty-four years since, Mr. Bullen was well known as an Orchid cultivator, being

then in the service of Mr. Turner, of Leicester, and when there he frequently enriched our columns with articles on the cultivation of those plants. Throughout the dreary times at the Glasgow garden, he maintained the plants in high condition, in spite of depressing circumstances, and was regarded by all who knew him as an excellent curator and a talented gardener.

The post vacated by his death is one of the best curatorships in the country. We understand that the appointment will rest with the Corporation of the City, who recently took over the management of the garden. Among the candidates mentioned is Mr. D. Dewar, the foreman of the herbaceous ground at Kew.

ENQUIRIES.

"He that questioneth much shall learn much."—BACON.

Will any reader kindly inform A. MACDONALD how it is that his Raspberries fruit principally on this year's canes, and the canes made last year are unfruitful? He has at the present time some of the canes of this season in flower, and others are bearing magnificent berries.

Would some of the readers of this Journal kindly oblige CHAS. C. HURST by giving the measurement of the largest Elm tree in Great Britain (measured by its diameter 5 to 6 feet from the ground), and if it be not an Elm, the measurement to be taken in the same manner.

THE WEATHER.

[By the term "accumulated temperature" is meant the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named; and this combined result is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

The districts indicated by number in the first column are the following:—
0, Scotland, N. Principal Wheat-producing Districts—
1, Scotland, E.; 2, England, N.E.; 3, England, E.;
4, Midland Counties; 5, England, S.
Principal Grazing, &c., Districts—6, Scotland, W.; 7, Ireland, N.W.; 8, England, S.W.; 9, Ireland, N.;
10, Ireland, S.; (* Channel Islands.)

THE PAST WEEK.

The following summary record of the weather for the week ending October 8, is furnished from the Meteorological Office:—

"The weather was in a very rainy and unsettled condition throughout the period, the rainfall at most of the eastern and south-eastern stations and in the north of Scotland being unusually heavy. Thunderstorms occurred at times, especially in the south-east.

"The temperature was below the mean, the deficit ranging between 2° and 4°. The highest of the maxima were recorded, as a rule, on the 4th, when they varied from 61° in 'England, S.,' and 60° in 'England, E.,' and the 'Channel Islands,' to 56° in 'Scotland, W.' and 'Ireland, N.' The lowest of the minima, which were registered either at the beginning or end of the week, ranged from 32° in 'Scotland, W.' and 'England, S.W.,' to 38° in 'Ireland, S.,' and to 41° in the 'Channel Islands.'

"The rainfall exceeded the mean in all districts, except 'Ireland, S.,' the excess in 'Scotland, N. and E.,' and 'England, E.,' being exceptionally large.

"The bright sunshine slightly exceeded the mean in 'England, S.W.,' and the 'Channel Islands,' but was considerably less in almost all other districts. The percentage of the possible amount of duration ranged from 40 in the 'Channel Islands,' 35 in 'England, S.W.,' and 30 in the 'Midland Counties,' to only 10 in 'Scotland, E.,' and 8 in 'Scotland, N.'"

MARKETS.

COVENT GARDEN, October 13.

TRADE dull. Cobbs easier. James Webber, Wholesale Apple Market.

The trade for best samples is improving, and are worth from 75s. to 80s., with a prospect of rising. Ordinary samples, 50s. to 60s., and not a good demand. J. B. Thomas.

NOTICES TO CORRESPONDENTS.

*** PHOTOGRAPHS, DRAWINGS, OR SPECIMENS.—We shall be pleased to receive from our Correspondents notes relating to interesting Gardens, together with Specimens or Illustrations of interesting Plants. Although circumstances prevent us in all cases from reproducing them, we are nevertheless glad to receive them, and as far as possible to utilise them for the benefit of our readers.

ALBUM FOR PRESERVING FERN FRONDS: C. L. Any bookbinder would make one for you if you furnished him with the particulars of size, &c.

BACK NUMBERS OF THE "GARDENERS' CHRONICLE": W. A. Y. These are sold at 3½d. each, post-free. All copies are out of print up to and including 1887.

CAPITAL FOR A MARKET GARDENER AND HARDY FRUIT GROWER: *Perplexed.* The usual estimated capital of a farmer for an arable or mixed farm is put at £10 per acre. We think that £15 would be nearer the mark, and a person going into fruit and vegetable farming, who cannot look for full returns from the land for the first two or three years, nor, indeed, for several years after taking possession, would need to have, at the least, £40 per acre of occupied land. Vegetables give quick returns, but the selling prices are low, unless you happen to have a good early crop of anything. Forced things pay well if produced in the best condition; these are Seakale, Rhubarb, Asparagus, Mushrooms, Mustard and Cress, Cucumbers, Tomatos, Beans, Chicory. Of course, if the occupier work hard early and late, and keep his workpeople well in hand, he may do with as little capital per acre as the farmer with his more simple methods of culture, but it is then very uphill work.

CARDIFF CHRYSANTHEMUM SOCIETY: *G. O. M.* The secretary is Mr. F. Searl, 21, Clive Road, Carton, Cardiff.

CARNATION: *Enquirer.* The too common Carnation fungus. There is no known cure short of burning every diseased plant.—*D., Chester.* We find the Carnation fungus, *Helminthosporium echinulatum*, in fine condition, but no grubs. See *Gardeners' Chronicle*, 1886, August 2.

CATERPILLAR: *P. P.* It must have escaped in transit, or become smashed beyond recognition. Was it a leaf miner? They are common on Chrysanthemum leaves. Kindly send again in a box.

CELERY: *F. B.* The Celery has "bolted," that is, it has begun to push up the flower-stalk. The seed was sown too early, or the plants have suffered from drought.

CORRECTION.—The address of Mr. John Stewart, whose article on steam heating appeared in our last issue is Cartvale, Paisley, not Cartnal, &c.

CRACKING OF PEARS: *Haynford.* This is due to the presence of a fungus, which destroys the vitality of the rind and outer portions of the flesh of the Pear, so that they cease to grow in proportion to the rest of the Pear, and are in consequence, cracked by the pressure of the growing portions. The name of the fungus is *Fusicladium pyrinum*. We are sorry not to be able to recommend anything beyond what you tried. In the young state of the fruit another year, it might be well to try spraying with sulphate of copper on the leaves and young fruit, but we hardly think the game would be worth the candle.

EUCHARIS: *J. A. B.* The large size is due to the union of two flowers.

GALVANIZED-IRON WIRE AND PLANTS: *A Lover of Flowers.* We do not understand how injury could occur if you have painted the wire, unless it be from friction. Can you send us a piece for inspection?

INSECTS, ORCHID ENEMIES: *W. H. White, Burford Lodge.* The bulbs of imported *Dendrobium Phalaenopsis* are attacked by the larvæ or grubs of a small beetle belonging to the family Calandrinæ. We cannot, however, find any grubs, larvæ, or beetles in the stems, and it is consequently necessary for you to examine carefully for any indications of the living parasites, which should be found and destroyed. *J. O. W.*

NAMES OF FRUITS: *C. W. Strickland.* Pear Triomphe de Jodoigne.—*T. R.* 1, Belle de Bruxelles; 2, Durondeau; 3, not recognized; 4, Beurré Superfin; 5, Josephine de Malines; 6, Van Mons Léon Leclerc.—*Alpha.* 1, Emile d'Heyst; 2, Doyenné Boussoch; 3, Alexandre Lambre; 4, Glout Moreau; 5, Napoléon; 6, Baronne de Mello.—*E. Roberts.* Kirke's Lord Nelson.—*W. Watson.* 1, Kerry Pippin; 2, Duchess of Oldenburg.—*Ed. G. Allen.* 1, Stone's or Loddington Seedling; 2, Emperor Alexander; 3, Cellini Pippin.—*W. Naish.* Emperor Alexander.—*W. Lazenby.* Large one, Gansell's Bergamot; small one, Comte de Lamy.—*R. Morrow.* Royal Somerset.—*A. T. S.* 1, Keawick Codlin; 2, Peach Apple; 3, New Hawthornden; 4, Beauty of Kent.—*E. Bennett.* 1, Warner's King; 2, Blenheim Orange; 3, Bnaton Russet; 4, Yorkshire Beauty.—*Paddy from Cork.* 1, Hoary Morning. *Walter Parker.* 1, Old Nonsuch; 2, not recognized; 3, King of the Pippins; 4, Ribston Pippin; 5, Lamb Abbey Pearmain; 6, not recognized; 7, Shepherd's Fame; 8, Potts' Seedling; 9, Beurré de Capiaumont; 10, Zephirin Gregoire; 11, Paradis d'Autonne.—*Reginald.* Old Nonsuch.—

T. S. 1, Peasgood's Nonsuch; 2 and 3, not recognized; 4, King of the Pippins; 5, Potts' Seedling; 6, Red Quarrenden; 7, Hollandbury; 8, Fearn's Pippin; 9, Mank's Codlin; 10, Ribston Pippin; 11, Worcester Pearmain; 12, Blenheim Orange.—*R. J. Sherring.* 1, unknown; 2, Adam's Pearmain; 3, Claygate Pearmain.—*V. S.* 1, unrecognized; 2, Red Astrachan; 3, Fearn's Pippin; 4, Old Nonpareil.—*F. B.* Plum: *Prunus inositia* (the Bullace).

NAMES OF PLANTS: *J. S.* *Datura Stramonium*, the Thorn Apple. It is a Solanad, and very poisonous.—*B. D. I.* *Retinospora filitica*; 2, *Abies nigra*; 3, *Cupressus Lawsoniana aurea*; 4, *Juniperus sinensis aurea*; 5, not recognized; 6, *Retinospora obtusa*; 7, *Retinospora obtusa* var. *pygma*; 8, *Thuja occidentalis*.—*C. Steele.* The fragment of immature *Agaric* is insufficient for determination. No spores are developed, so that even the section to which it belongs is uncertain (*M. C. Cooke*).—*C. B. G.* *Rhus Cotinus*, the Wig-Plant.—*J. W.* *Helianthus rigidus*. The Ficus and the fruit next week.—*R. S.* 1, *Saponaria officinalis* (Caryophyllacæ). Britain; 2, *Aster novæ-angliæ* variety, Composite, United States; 3, *Desfontainea spinosa*; 4, *Aster Linosyris*, Composite, Britain.—*I. Q.* *Catasetum tridentatum*.—*C. H.* 1, *Adiantum Farleyense*; 2, *Cheilanthes elegans*; 3, *Pteris serrulata cristata*; 4, *Pteris serrulata*; 5, *Adiantum cuneatum* variety; 6, *Polystichum angulare*.—*S. O.* *Epidendrum atropurpureum* (var. *Randt*).—*H. T. R.* *Odontoglossum tripudians*.—*K. H.* *Farleigh*. *Catasetum macrocarpum*.—*C. P.* *Catasetum macrocarpum*.—*A. H. B. F. B.* 1, *Veronica Traversii*; *Abelia rupestris*; 3, *Sedum acre*; 4, *Saxifraga japonica*; 5, *Sedum carneum variegatum*; 6, too wet or moist, perhaps; should be grown in a basket.—*W. Naish.* 1, *Daboecia polifolia* and white variety; 2, *Nerium undulata*; 3, *Epidendrum variegatum*; *J. M.* 200, *Athyrium filix-femina*; 150 *Lastrea filix-mas*, var. *abbreviata cristata*; 60, *Lastrea spinulosa*; 40 *Lastrea recurva*; 29, *Lastrea rigida*; 400, *Athyrium filix-femina* var.—*J. P.* *Cymbidium giganteum* and *Vanda tricolor insignis*.—*A. B.* *Solidago canadensis*. Fruits next week.—*E. C. J.* *Calycanthus occidentalis*.

ORCHIDS: *J. T.* *Cattleya chocoensis* which is presumably a form of *C. Trianae*, should succeed under the same treatment as the other *Cattleyas* in the house. Perhaps it does not like its position in the house. Examine the potting compost and drainage without disturbing them much. *Paphinia grandis* must be kept in the East India-house, suspended in a basket. The night temperature might be 62° to 63° for a month longer, and then 60° till the middle of February. By day 70° to 75°.

SCALE ON MESEMBRYANTHEMUM: *C. N.* *Pulvinaria mesembryanthemi*; see *Signoret Essai sur les Cochenilles*.

SEEDLING CACTUS DAHLIA: *R. M.* A beautiful coloured flower, and worth preservation as a decorative variety, if the plant is floriferous.

SITUATION IN A BOTANICAL GARDEN ABROAD: *J. T. Rose.* You should proceed by making application to the Superintendent at Port Elisabeth. Java is a dangerous climate for a European, and you would, moreover, be obliged to learn the Dutch language.

STRAWBERRIES POTTED SEPTEMBER 1: *R. Gen. B.* If the plants fill their pots (48's) by the end of the present month, they may be forced early; but it is now too late to repot them into 32's, the season of growth being too short to allow of the roots permeating the whole of the new soil. Had the runners been potted early in August, and repotted one month later into 32's, these pots would have become filled with roots by the end of October. You began too late.

TO FLORISTS.—A Young Lady wishes re-engagement. Thoroughly experienced in Wreath, Cross, Post, and Spray Making. Excellent references.—**B. W.**, 65, Broad Street, Worcester.

HOLLOWAY'S PILLS.—This cooling Medicine has the happiest effect when the blood is overheated and a tendency to inflammatory action is set up in the system; one Pill taken shortly before dinner does away with the indigestion, fullness, and flatulency—indications of a weak stomach or disordered liver. A few Pills taken at bedtime act as alteratives and aperients; they not only relieve the bowels, but regulate every organ connected with them, overcome all acid humours, and encourage a free supply of all the secretions essential to our well-being. Holloway's Pills thoroughly cleanse and perfectly regulate the circulation, and beget a feeling of comfort in hot climates and high temperatures, which is most desirable for preservation of health.

THE IMPROVED GARDEN GULLY
(VINCE'S PATENT).

This useful invention is a great improvement on the ordinary Garden Grating, and is especially suitable for hilly walks and drives. As they never get stopped by rubbish or sand they effectually prevent the washing away of the gravel in heavy storms, and they save half the labour in cleaning out the cesspools. The prices are:—
6-in., 1s. 6d.; 8-in., 2s.; 10-in., 3s.; 12-in., 6s. 6d.; 15-in., 8s.
(The larger sizes are very strong for carriage drives.)

FIXED.

Full Particulars on application. Testimonials:—

From Mr. J. WILLARD, Head Gardener to the BARONESS BURDETT-COUTTS, Holly Lodge Gardens, Highgate, N., July 12, 1892.—"Dear Sirs, Having given your Improved Garden Gully a fair trial, I may say that it proves in use all that you claim for it, and in my opinion has, for the sides of walks and drives, many advantages over the ordinary grating. Perhaps the best proof I can give you of this is that, as opportunity offers, I intend to use them instead of gratings. Faithfully yours, J. WILLARD."—To Messrs. VINCE & VINE.

From W. WALTON, Esq., Secretary to the LONDON CEMETERY COMPANY. The London Cemetery Company, 29, New Bridge Street, Blackfriars, E.C., July 25, 1892.—"To Messrs. Vince & Vine, Highgate. I am very happy to testify that your Patent Garden Gully-Frames in lieu of the old fashioned gratings answer admirably. They were by my authority fixed in a new pathway made in Highgate Cemetery, and in the recent thunder showers they were severely tested and were

most effectual in preventing the scouring of the gravel. At the inspection my Directors were much pleased with them, and gave instructions that they were to be used when required at Nunhead Cemetery.—I am, yours truly, W. WALTON, Secretary."

From Messrs. CUTBUSH AND SON, Highgate and Barnet Nurseries.—"Highgate Nurseries, London, July 27, 1892.—Dear Sirs,—Referring to the Improved Garden Gully you fixed for us some months ago, we are glad to say it answers admirably. As you are aware, our Nurseries here are very hilly, and during the recent storms all the ordinary gullies were blocked, whereas yours was in good working order. We shall not hesitate to recommend the same to anyone requiring the gullies for sides of paths and carriage-drives, and we feel certain, when it is known, there will be a great demand.—We are, yours faithfully, WM. CUTBUSH AND SON.—Messrs. VINCE & VINE."

VINCE & VINE, 58, Chester Road, Upper Holloway, London, N.

ODONTOGLOSSUM CRISPUM ALEXANDRÆ.

BEST VARIETY.

GUILLERMO KALBREYER begs to offer the above well-known and justly-prized Orchid at the following prices, free on board of Royal Mail Company's steamers, at Savanilla:—£40 per 1000 good and healthy pieces.

G. K. also can supply:—

ODONTOGLOSSUM LUTEO-PURPUREUM,
" CUSPIDATUM PLATIGLOSSUM,
£36 per 1000.

CATTLEYA TRIANÆ, best variety, £8 per case.

Each case contains from fifty to sixty good, strong pieces, and measures about 20 inches by 34 inches.

The plants are packed with the greatest care and best method, but under no circumstances will G. K. hold himself responsible for the state of plants on their arrival in Europe. Conditions:—All consignments are shipped entirely at Buyer's risk and expense from port of shipment. Plants ordered must be paid for on receipt of bill of lading to Messrs. ROESING BROTHERS AND CO., 10, Basinghall Street, London, E.C., who will then give orders for forwarding the consignment to the Purchaser.

The best time for dispatching Orchids from here, and to establish them with the best advantage in Europe, are the months—December to April.

The Alexandra Palace, Muswell Hill. PRELIMINARY NOTICE.

MESSRS. PROTHEROE AND MORRIS beg to announce that they have been favoured with instructions to sell by AUCTION, on the Premises above, at an early date, the whole of the valuable SPECIMEN PLANTS in the Conservatory and Italian Garden. The plants are probably too well known to need description, but the principal Specimens will be mentioned in next week's advertisement.

East Dulwich. - Wednesday Next. IMPORTANT SALE of ESTABLISHED and IMPORTED ORCHIDS, by order of Messrs. Seeger & Tropp, Limited, in consequence of the Dissolution of Partnership.

MESSRS. PROTHEROE AND MORRIS will sell by AUCTION, on the Premises, the Orchid Nurseries, East Dulwich, a short distance from the East Dulwich Station, on WEDNESDAY NEXT, October 26, at half-past 12 o'clock, a large collection of valuable and well-grown ESTABLISHED ORCHIDS. Amongst the principal plants the following may be mentioned: - Cypripedium Lemoinei, Sobralia macrantha, Woolley's var. Dendrobium nobile nobiliss Lælia purpurata alba Brassavola (Lælia) Digbyana Grammatophyllum Seegerianum Lindemannia Pescatorei Cattleya intermedia alba Lælia elegans Schilleriana Colia macrostachya grandiflora Cattleya Reineckiana, Rucker's var. Masdevallia Harryana miniata Solralia Ruckeri Cattleya guttata phœnicoptera Mossie Hardyana Schofieldiana Lælia anceps Schroderæ Angulosa Ruckeri sanguinea And many other Rare and Beautiful ORCHIDS. Also an importation of SACCOLABIUM ILLUSTRE, a grand and noble species; ODONTOGLOSSUM ALEXANDRE and O. LUTEO-PURPUREUM, DENDROBIUM FORMOSUM GIGANTEUM, &c. May be viewed. Catalogues may be had on the Premises; and of the Auctioneers, 67 and 68, Cheapside, London, E.C.

Friday Next. MESSRS. PROTHEROE AND MORRIS will sell by AUCTION, at their Rooms, 67 and 68, Cheapside, London, E.C., on FRIDAY NEXT, October 28, at half-past 12 o'clock precisely, by order of Mr. J. Sander - ONE HUNDRED CATTLEYAS FROM SANTAYUNI,

From where the truly magnificent CATTLEYA OWENIANA, C. WARSCEWICZI ROTHSCHILDIANA (the wonderful purple variety), and the grand form lately flowered by Mr. Le Doux were obtained. They have already obtained a recognised place in the front rank of gorgeous Cattleyas. The plants now offered are perfectly safe, sound, and healthy, and we expect to be able soon to congratulate buyers on the possession of some of the loveliest gems the Orchid world has ever produced.

LÆLIA PURPURATA and VARIETIES.

A GRAND IMPORTATION, JUST ARRIVED. The plants are full of sound leaves and eyes, and could not possibly be in finer order. We draw special attention to this splendid lot of Lælia purpurata, collected in the very district that produced Lælia Gotoiana, for which our man was particularly dispatched; they were found growing intermixed with these purpuratas, and our collector states that he was unable to separate them, as most had flowered, and only old and dilapidated blooms were left on many to guide him. We offer them as received, and our supporters have the benefit of securing the fine things that are plentiful among them.

A DISTINCT-LOOKING AND SCARCE CYPRI-PEDIUM, PROVISIONALLY NAMED ANNAMENSE, Flowers white and citron, with purple spots, and of a perfect form.

ONCIDIUM AMPLIATUM MAJUS, The true majus variety, in splendid, well-leaved plants.

MILTONIA FLAVESCENS (syn. M. Claesiana), CATTLEYA ACLANDIÆ, The finest variety of this hitherto scarce Orchid ever seen.

CATTLEYA VICTORIA REGINA, THE MOST SUPERB CATTLEYA of MODERN INTRODUCTION. FINER THAN THE FINEST LÆLIA ELEGANS EVER SEEN. Splendid importation, just received in simply grand order.

CATTLEYA ALEXANDRE, The great umbel-flowered Cattleya. A splendid lot.

ZYGOPETALUM SPECIES, A distinct Crimson, Blue, and Green flower. STANHOPEA NIVEA.

The largest and finest of all the white Stanhopeas. ONCHIUM SANDERIANUM (provisionally named), In the way of O. Rogersii, producing enormous sprays of Gold and White flowers.

ONCIDIUM UROPHYLLUM, And many other choice and rare ORCHIDS. On view morning of Sale, and Catalogues had.

Feltham. - Preliminary Notice. By order of Messrs. C. Lee & Son.

MESSRS. PROTHEROE AND MORRIS will sell by AUCTION on the Premises, the Nurseries, Feltham, on FRIDAY, November 11, CONIFERS of the best kinds, Green and other Hollies, Laurels, Privet, &c. Full particulars will appear in future announcements.

BEAUTY OF BATH

(THE COMING APPLE).

THIS is the finest, New, First Early Dessert Apple introduced for many years. It has gained honours at every Exhibition where shown; First-class Certificate Royal Horticultural Society; and First Prize for the Best Dessert Apple in competition with thirty-five dishes staged, and was included in the First Prize Dish of Dessert Apples at the recent International Fruit Exhibition, Earl's Court, open to all England, August 16 and 27, 1892. Mr. HORNE, of Perry Hill, Cliffe, near Rochester, holds the largest stock of this magnificent Early Dessert Apple in England.

On **WEDNESDAY NEXT, October 26,**
Messrs. PROTHEROE & MORRIS

Will hold the **Fourth Great Annual Sale** on the Premises, as above, adjoining Cliffe Station, South Eastern Railway, of **100,000 FRUIT TREES,** consisting of 35,000 Apples, Pears, Plums, and Cherries of all the leading Market sorts; 8,000 Apples of different kinds on English Paradise; 1,500 Standard, Half-Standard, and Maidens, Bismark, Lady Sudeley, and Jubilee; **5,000 Beauty of Bath** are included; 50,000 Baldwin Black Currant; 4,000 New Reds; 12,000 Bob and Lad Gooseberries; 5,000 celebrated John Ruskin Strawberry, and others in large and small pots, for forcing; 20,000 Ruskin, from open ground; 20,000 Paxtons; 20,000 Nobles; 20,000 French Connover's Colossal Asparagus, 3-yr. old; 50,000 Rainham Cabbage Plants, &c.

Catalogues may be had on the Premises; or, of the Auctioneers, 67, Cheapside, London, E.C., who will be pleased to execute commissions for Gentlemen who cannot attend, and desire to call special attention to this important Annual Sale. It is seldom an opportunity is offered of securing Fruit Trees and Bushes in such large quantities. Fruit Growers and others interested in Planting this season are invited to inspect the extensive Stock, and to attend the Sale.

For the convenience of buyers at a distance, Mr. Horne will lift and put on rail all lots, after the Sale, free of cost.

May be viewed seven days prior to the Sale, and Catalogues obtained on the Premises, and of the Auctioneers, at either of their Offices at Chertsey, Weybridge Station, and opposite the Station entrance, Walton-on-Thames.

WANTED, to RENT, a small NURSERY and FLORIST'S, with little or no Stock. THE GARDENER, 117, Tulse Hill, Brixton, S.W.

To Nurserymen and Florists commencing Business. HAMPTON-ON-THAMES, on the Marling Park Estate, free from London fogs, a deep rich Loam, the favourite neighbourhood for Growers. FREEHOLD LAND for SALE, on easy system of Purchase, or to be LET on Lease. For full particulars apply to Mr. FRED. G. HUGHES, Surveyor, The E-state Office as above.

Crown Lands, Hampton Court, Middlesex. TO BE LET, with immediate possession, about 11 acres of productive KITCHEN and ORCHARD GARDENS, adjacent to Hampton Court Palace, and close to Hampton Court Station on the South-Western Railway, with the Vineries, Peach Houses, Forcing Pits, Tomato Houses, and the Cottage, Shop, Store-room for Fruit, and other Buildings thereon.

The Gardens are walled in, and subdivided with internal walls, and the walls and grounds are well stocked with Fruit Trees, and Currant and other Bushes. Apply to Messrs. CLUTTON, 9, Whitehall Place, London, S.W.

TO BE SOLD or LET, within a short distance of the Liverpool and St. Helens Markets, a well-arranged MARKET GARDEN, with 18,000 sq. feet of Glass, in twelve Greenhouses, well-heated with Hot-water throughout, and in excellent condition. Stock may be taken at a Valuation. Also Two Convenient DWELLING-HOUSES, together with good Shippin for twelve Cows, and three-stall Stable, which can be Let Separately.

Apply, Mrs. BESLEY, 31, Kemble Street, Prescot. Warwickshire.—Erdington Hall Estate.

TO BE LET, an excellent FARM, situate within 3 miles of Stephenson Place, Birmingham. There is a large House and extensive Buildings, and the Land is well adapted for Market Gardening, being close to the City. It consists of Arable and Pasture Land, and is about 173 Acres. For Rent and Particulars, apply to Messrs. J. C. FOWKE AND SON, Solicitors, 120, Colmore Row, Birmingham.

Herts.—11 miles from London. To GENTLEMEN and FLORISTS. TO BE LET, DETACHED RESIDENCE, and an acre and three-quarters of land, with seven substantial Greenhouses, all well-heated. Lease seventeen years to run. Rent, £79. Any reasonable offer entertained for the purchase of the Greenhouses. Full particulars of Messrs. PROTHEROE AND MORRIS, 67 and 68, Cheapside, E.C. (7788.)

TO BE LET, in the suburbs of London, 8 miles from Covent Garden, a compact NURSERY and good DWELLING-HOUSE, ¼ Acre of Land, 5 Greenhouses (altogether 350 feet run) and range of Lights, well Heated and in good Working Order. Stocked with good saleable stuff. On Lease seven, fourteen, or twenty-one years. Rent £30. Stock at valuation.—For further particulars apply, G. E., *Gardeners' Chronicle* Office, 41, Wellington Street, Strand, W.C.

TO BE SOLD, or LET, with Immediate Possession, YORK NURSERY, St. Ann's Road, Stamford Hill, London, N. Rather more than one acre and a quarter, with four-roomed House and Out Offices, 11 Greenhouses, &c., Apply on the Premises to Mr. S. J. COLDRIDGE.

£8.50—FREEHOLD NURSERY, S.E.— Good neighbourhood, well situated; Dwelling-House, Seven large Rooms; Five Greenhouses, fitted with Heating Apparatus; well stocked.—BROWN, Ramsey Villa, Weymouth Street, Watford.

NURSERY and GARDENING BUSINESS for DISPOSAL.—Four Heated Houses, well-stocked; 2½ Acres; good working order; lease; rent, £24. Price, as it stands, £750; bargain. — Apply, DILNOTT STOKES AND FUGLE, Business Agents, Tunbridge Wells.

The Nurseries, Staines Road, Hounslow. IN BANKRUPTCY *re* J. AND G. BANNISTER. By order of the Official Receiver. SALE OF THE LEASE and the whole of the GLASS GREENHOUSES, STOCK, and UTENSILS IN TRADE, in one lot, as a going concern.

MESSRS. PROTHEROE AND MORRIS are instructed to SELL the above by Private Treaty. The premises comprise one large block of land, with fifteen Greenhouses; also another block of land, with one large Greenhouse, 600 feet in length. The whole of the Stock will be included in the purchase. Offers to be made at once. Full particulars of Messrs. PROTHEROE AND MORRIS, 67 & 68, Cheapside, London, E.C.

FOR SALE, a very compact FREEHOLD NURSERY, of about ¾ of an Acre, within 12 miles of London, West District, S.W.R., with 5 Forcing-houses, and every convenience, constant supply of water, &c. Has done a good regular Cut Flower Business round West End for years. The whole, including Plants, Stock, Implements, Goodwill as a Going Concern to be Disposed of Cheap, to an immediate Purchaser, as present Proprietor is retiring from the Growing Business after a successful period. This is a rare chance seldom met with. Most suitable for a good Gardener wishing to start in a sound undertaking. Apply for further particulars, S. V., *Gardeners' Chronicle* Office, 41, Wellington Street, Strand, W.C.

200 GARDEN LIGHTS (New).—6 feet by 4 feet, very strong Red Deal Framework, 3 inch, by 2 inch, thick, Sash-bars, 2 inch, by 1½ inch; ditto, including Iron Bar across, and Painted, 3s. 11d. each; if supplied with 21-oz. Glass, 8s. each.—D. HORROCK, Tyldesley, Manchester.

SADDLE BOILER.—Has been in use about three years; 4 feet long, 21 in. by 22 in. inside arch; been replaced by a larger. Price £5, free on rails. Complete set of WELL-BORING TOOLS, only been used for boring two wells. What offers? C. WHITE AND CO., Crescent Street, Grimsby.

GARDENERS' CHRONICLE.—To be Sold, in bound Vols., 1859 to 1889, inclusive, and unbound from that date to present time, with probably a few numbers missing.—Address offers to THE RECTOR, Cosgrove Rectory, Stony Stratford.

FOR ORCHIDS and GARDENERS to Grow Them, apply to SANDER'S, St. Albans. The finest stock of Orchids in the World.—30 minutes from St. Pancras.

TWO GREAT SALES.

PROTHEROE & MORRIS,
67 and 68, CHEAPSIDE, LONDON,
Will SELL, by order of F. SANDER & CO.,
ST. ALBANS, ON

TUESDAY, OCTOBER 25,
500 grand Plants and Specimens of the
TRUE OLD LABIATA,

in SHEATH, in BUD, in FLOWER—a superb, leafy,
healthy lot, well-established, and growing with
vigour—an unprecedented sight.

FRIDAY, OCTOBER 28.

ONE HUNDRED CATTLEYSAS,

From SANTAYUNI, from which the truly magnificent CATTLEYA OWENIANA, C. WANSCEWICZII ROTHSCHILDIANA, the wonderful purple variety, and the grand form lately flowered by MR. LE DOUX. They have already obtained a recognised place in the front rank of gorgeous Cattleyas. The plants now offered are perfectly safe, sound, and healthy, and we expect to be able soon to congratulate buyers on the possession of some of the loveliest gems the Orchid World has ever produced.

LÆLIA PURPURATA AND VARIETIES,

A grand importation just arrived. The plants are full of sound leaves and eyes, and could not possibly be in finer order.

We draw SPECIAL ATTENTION to this splendid lot of *Lælia purpurata* collected in the very district that produced *Lælia Gottoiana*, for which our man was particularly despatched. They were found growing intermixed with these *purpuratas*, and our collector states that he was unable to separate them as most had flowered, and only old and dilapidated blooms were left on many to guide him. We offer them as received, and our supporters have the benefit of securing the fine things that are plentiful among them.

A Distinct-looking and Scarce CYPRIPEDIUM, provisionally named

ANNAMENSE

Flowers White and Citron, with Purple Spots, and of a perfect form.

ONCIDIUM AMPLIATUM MAJUS

The True Majus Variety, in splendid well-leaved Plants.

MILTONIA FLAVESCENS

(Syn. M. CLAESIANA).

CATTLEYA ACLANDIÆ.

The Finest Variety of this hitherto scarce Orchid ever seen.

CATTLEYA VICTORIA REGINA.

The most superb Cattleya of modern introduction. Finer than the finest *Lælia elegans* ever seen. Splendid importation, just received in simply grand order.

CATTLEYA ALEXANDRÆ.

The great Umbel-flowered Cattleya—a splendid lot.

ZYGOPETALUM SPECIES.

A distinct Crimson, Blue, and Green Flower.

STANHOPEA NIVEA.

The Largest and Finest of all the White Stanhopeas.

ONCIDIUM SANDERIANUM.

(PROVISIONALLY NAMED),

In the way of O. ROGERSII, producing enormous Sprays of Gold and White Flowers.

ONCIDIUM UROPHYLLUM.

And many other Choice and Rare Orchids.

THE

Gardeners' Chronicle.

SATURDAY, OCTOBER 22, 1892.

BLITHFIELD.

BLITHFIELD, so called from the river Blythe, is the ancestral home of the Bagots, one of the oldest Staffordshire families, and has sheltered the head of the family for 400 years. The baronetcy dates from 1627, and the peerage (Lord Bagot of Blithfield) from 1780. There has never been any danger of the family dying out, for one "Ludokin Bagot," on the authority of a tablet in the pretty church near the hall, had nineteen children, who all survived him. The late lord must have been a very careful or else a very eccentric peer. In the coach-house at the expensively fitted-up stables, is an old-fashioned narrow earriage, which only holds two people, one facing the other; instead of wheels, it is mounted on rollers, one in front, and two behind. The reason for the construction of this queer vehicle, was to convey two old ladies, relatives of this lord, from the rectory to the hall for dinner, and to take them back. The rollers were intended to obliterate all the pony tracks.

The park is very extensive, and contains some very old trees. The oldest are to be found in the Deer Park—Bagot's Park it is called. Here is the far-famed Beggar's Oak, figured in the *Sylva Britannica*. As it is still vigorous and wide-spreading, it is likely to last another century at least. Above-ground roots extend from it in all directions, and these form a circuit of 83 yards. The girth taken above where the roots join the trunk, which is a few inches from 4 feet, is 28 feet. Another Oak in perfect health, and likely to last two centuries, was 24 feet 8 inches. I always have an eye for big Oaks, and I never saw so many, more than 20 feet in girth, than in this Bagot's Park. But it must be confessed that many of them are quite hollow, and fast falling into decay. The Mocoas Oak on the banks of the Wye is said to be 36 feet in girth, but I doubt if it is sound all through, as the Beggar's Oak seems to be. In addition to the old trees, the pretty stream of the Blythe, which in one place widens out into a big pool, and the many copses and bits of woodland diversify the surface of the park in an attractive manner.

The pleasure-grounds on two sides, the west and south, of the house, are very interesting from their quaint, old-fashioned air, or, rather, appearance. Approaching it, as I did, from the kitchen garden, the first thing that compels attention is a straight walk leading past two magnificent Cedars of Lebanon, towering up to a great height, and spreading wide their branches. As the bottom branches are out off,

one easily sees the immense proportions of the trunk and main branches. Next to these giants is a *Cedrus atlantica*, which has emulated the manner of growth of the Libani, and but for its glaucous colour could hardly be distinguished. This tree bids fair to eclipse its rivals. It was one of the first ever introduced, and was sent to a former Lord Bagot by a Liverpool firm. Passing on, we come to a small orchard, which in spring must be lovely, and then to a lawn with long beds of herbaceous flowers, which looked very bright and gay. The old Strawberry garden, as it used to be called, is now planted with herbaceous flowers, and a series of iron arches going in the direction of the house are festooned thickly with Vines, Clematis, Jasmynes, Roses, and other plants, that can be made to climb. Opposite this is a rectangular tank, with water-plants growing into it, and some Fern-girt rockwork. This part of the grounds cannot have been much changed from old times; it is to be hoped no one will attempt to improve it. Passing round the house, we come to the flower garden in a quadrangle, enclosed on three sides by the building, and open to the pleasure-grounds on the other. The bedding was very well done, and on close examination did not seem much affected by the inclement season; this is probably owing to the sheltered position. The pleasure grounds here consist of walks among lawns and shrubberies, and extend for 14 acres. Besides the Cedars mentioned, there are two fine Beeches; one a tall wide-spreading example of the Fern-leaved Beech, and another a curious departure from the ordinary variety, which has assumed a weeping form, some of the branches drooping from 15 to 20 feet. *Ampelopsis Veitchii* was growing most rampantly on the hall, clutching nearly all one side with its tenacious claws.

The kitchen garden was in a high state of cultivation. As the subsoil is a cold damp clay, and the climate here is, for the greater part of the year, adverse to vegetable growth, this fact is the more creditable to Mr. Bannerman. Brussels Sprouts, Celery, Broccoli, and Strawberries were making luxuriant growth, Plums were a good crop, and unlike other gardens there was a fair sprinkling of Pears. Fruit growing is likewise a success here. Barrington Peach comes to an enormous size on one tree, and Mr. Bannerman took the 1st prize at Moseley with fruit gathered from it. *Vagabond*.

NEW OR NOTEWORTHY PLANTS.

ALBUCA (LEPTOSTYLA) BUCHANANI,
*Baker, n. sp.**

THE section *Leptostyla* forms a connecting-link between *Ornithogalum* and *Albuca*, with the subulate style of the former and cucullate inner perianth segments and stamens of the latter. The present plant was discovered by Mr. John Buchanan, C.M.G., Acting Consul at Nyassa, who has made large botanical collections in the Shiri highlands, and has just forwarded to the Kew Herbarium a new set of nearly 1500 numbers. He presented bulbs of the present plant to the Royal Gardens, and it has now flowered for the first time. It is nearly allied to *A. Wakefieldii*, Baker, in *Botanical Magazine*, t. 6129, and *A. Alleneæ*, Baker.

* *Albuca (Leptostyla) Buchananii*, Baker, n. sp.—Bulbo parvo ovoideo; foliis circiter 4 linearibus viridibus facie canaliculatis margine obscure ciliatis; scapo gracili elongato; racemo laxo multifloro; pedicellis brevibus ascendentibus; bracteis lanceolatis; periantho luteolo oblongo; segmentis linearibus, interioribus apice cucullatis; staminibus periantho paulo brevioribus; stylo elongato subulato. *J. G. Baker*

Bulb small, ovoid. Leaves about four to a bulb, linear, acuminate, erect, 1 foot or 1½ foot long, bright green, channelled down the face, obscurely ciliated on the margin. Scape very slender, terete, as long as the leaves. Raceme simple, many-flowered, 3 to 4 inches long; pedicels erect, ¼ to ½ inch long; bracts lanceolate, as long as the pedicels. Perianth oblong, greenish-yellow, ½ inch long; segments linear-oblong, the three inner inflexed at the tip. Stamens nearly as long as the perianth; anthers oblong, the three inner smaller than the three outer; filaments linear, conduplicate above the ovate base, which is adpressed to the ovary. Ovary small, ovate; style subulate, yellow, ½ inch long. *J. G. Baker.*

CATASETUM HOOKERI, Lindl., ♂ AND ♀.

Catasetum Hookeri is a Brazilian species, which was described by Lindley upwards of sixty years ago in his *Collectanea Botanica*, t. 40, from a dried specimen, since which time it seems to have been quite lost sight of. It has now reappeared among the recent large importations of Brazilian plants, and has flowered in several different collections. The female flowers, hitherto unknown, have now appeared in the Kew collection, on a plant presented by Messrs. F. Sander & Co., of St. Albans. There are two males and two females on the same raceme. In both sexes the flowers are green. The females are very similar in structure to those of several other species, the lip invariably being uppermost, and the sepals and petals spreading. In the males the lip is also superior, somewhat hood-shaped, and with acute apex, while the sepals and petals are connivent underneath. The two antennæ are parallel within the lip. The male racemes are long and arching, and bear numerous flowers. There are eighteen species of *Catasetum* of which both sexes are now known. *R. A. Rolfe.*

SOILS MADE WARMER BY DRAINAGE.

THE amount of heat in the soil is a matter of the highest importance to the gardener. In some soils there is an obstacle to the entrance of air and warmth to its lower parts, and that obstacle is the presence of standing water.

The practical gardener need not be told that heat has a great influence upon the germination of seeds, and the growth of plants. A certain amount of this element in the soil is essential to germination and growth. A certain quantity is also necessary to the decomposition of carbonic acid by plants, and the nitrification of plant-food in the soil. Therefore, if the temperature of our soils can be raised during the period of active early growth, plants will progress faster towards maturity.

All our cultivated plants require for vigorous life a soil in which moisture is present, but not in the form of standing water. If the latter is the case, the plant-roots can only penetrate the soil to the depth at which the water stands. There are several practicable means for increasing the warmth of the soil, and drainage is one of them.

Drained soils are warmer than undrained ones, because much of the water which passes through them would otherwise be evaporated; and this evaporation, it must be remembered, requires enough heat to convert the water into vapour. The amount of heat thus used is naturally large. It has been estimated to be equal to that produced by burning two-thirds of a ton of coal per day, for each acre of land, on an average throughout the year. If this heat were not absorbed by the water, it would be largely, if not entirely, absorbed by the soil. The specific heat of water is greater than that of soil—five times as great as humus, seven times as great as loam, eight times as great as clay, and ten times as great as sand. Accordingly, more heat is required to warm up a certain weight of water than to raise the same weight of soil to an equal temperature.

As drains, therefore, remove an excess of water from the soil in the spring months at least, they remove water that otherwise would take heat from

the soil. More than this, water is a poor conductor of heat, and when the soil is wet, as in the spring months of the year, the warmth will penetrate much more slowly than if the excess of moisture were removed.

The advantage to the gardener of increasing the warmth of the soil he cultivates in the spring months, would be, that he would get plants started several days earlier, and their growth would be more rapid.

It has been recorded that there is a difference of from 10° to 15° in the temperature of drained and undrained soil, and the constantly higher temperature of drained soils is doubtless responsible for much of the larger growths upon them, and often would, alone, pay for the operation of draining.

The principal alterations which the soil undergoes through the removal of stagnant water, may be summarised as follows:—(a). Wet soil becomes drier. (b). Cold soil becomes warmer, for it now receives the full benefit of the heat of the sun and air; while previously a great part of this was expended in the evaporation of water, and could not produce a heating effect. Drained soils have a double advantage in regard to temperature, for they absorb heat more quickly than wet ones, and they do not part with it so readily. (c). Heavy soil becomes looser, more crumbly and softer; when it dries finer cracks are formed than in undrained tenacious soils, and it is more easily worked. (d). Sluggish soil becomes more active and powerful for being more open and warmer, the three great natural processes by which the food for plants is prepared and rendered soluble—weathering, decay, and nitrification—proceed more rapidly and actively, and to a greater depth down into the subsoil. Hence, the same quantity of a manure gives a higher return on drained than on quite undrained soils. (e). Finally, soil further becomes more certain in its returns. As is evident, the gardener by drainage changes an uncertain and less fertile, into a more certain and far more productive and profitable soil, rendering it, to a certain degree, independent of adverse weather.

As long as a soil is wet, a great portion of the heat of the sun's rays falling upon it is ineffectual, because they combine with the water, and convert this into vapour. Watery vapour is to be regarded as a combination of liquid water with a larger quantity of heat; but this heat is no longer sensible to the touch, and therefore it has been called latent, or fixed heat; it consequently cannot any longer contribute to the warming of the soil from which the watery vapour is given off. Direct experiment has given the following increase of heat under equal sunlight in:—

Soils.	Moist.	Dry.
	Fahr.	Fahr.
Calcareous soils	18°	32·4°
Sandy and clay soils	21·6°	34·2°
Humus and loamy soils	32·4°	39°

It is clear from the data thus given, as well as from many phenomena of the garden, that draining a wet-bottomed soil may render it not only drier but warmer, and irrigating a hot, dry soil renders it not merely moister but cooler. *J. J. Willis, Harpenden.*

NERINES.

FROM Mr. G. C. Van Tubergen, jun., of Haarlem, we have received a boxful of cut flowers of various *Nerines*, of the brilliancy of which it is almost impossible to speak in fitting terms without seeming to incur the charge of exaggeration.

In colour, they range from white through pink and rose-coloured to orange and scarlet, while some have a violet tinge. Measured across the truss, they range from about 1½ inch (4 to 5 cm.), in the case of *N. pancratioidea* to 7 inches (18 cm.), in the case of *N. Fothergilli* major. In addition to the size and colour, the latter, not to be adequately described in words, the points of difference are to be seen in the

relative length of the pedicel and of the flower; in the form of the flower, cup-shaped, funnel-shaped, regular or slightly two-lipped; in the undulation or evenness of the margin of the perianth-segments, the straight or curved direction of the

lip, the stamens and styles being curved; the anthers mature before the stigma. Of course, all this indicates the necessity for insect-visitation in the wild state, and shows what a chance the hybridiser has, and of which, indeed, he has availed himself.

N. pancratioides of Baker, in the *Gardeners' Chronicle*, November 14, 1891; with cylindrical scapes of the thickness of a goose-quill, bearing at the top two oblong acuminate, deflexed bracts surrounding a many-flowered truss, the outer flowers

FIG. 75.—ENCEPHALARTOS ALTENSTEINII: SHOWING FOLIAGE AND SEED CONES MUCH REDUCED. (SEE P. 496)

stamens and style, and in the length of these organs relatively to the perianth-segments. Where the flower is cup-shaped and the stamens are straight, the flower is likely to be regular, but in the funnel-shaped flowers the three or the four upper segments often range themselves together on one side, the others falling to the other side, and forming a lower

Those who are interested in the botany of the genus will find a classified description of all the species and varieties in some articles by Mr. Baker in our columns, December 19, 1885, p. 779, and December 26, 1885, p. 810.

Taking the lighter-coloured forms first, and proceeding to the darker ones, we have:—

of which open first (centripetal). The white flowers (including the ovary), are rather less than 1 inch long (25 mm.). Segments linear with a green midrib, the outer ones apiculate. Between the base of the segments and the base of the stamens is a row of small, toothed fleshy whitish scales, which do not occur in any of the other forms. Of the six stamens the three outer

are at first shorter than the three inner, which though the last to be developed, overtake the earlier ones in the course of development. Anthers linear purple; style columnar, with three furrows and a blunt-lobed stigma. The pedicel, ovary, and part of the outer surface of the outer flower segments are thickly covered with translucent peg-like glands or hairs, which are, so far as we have seen, peculiar to this species, which is so distinct that we should not be surprised, if when more fully known, it will be found to belong to another genus.

N. pudica.—Scape slender. Flowers, $1\frac{1}{2}$ inch (4 cm.) across, funnel-shaped, white flushed with rose, segments oblanceolate acute, more than $\frac{1}{4}$ inch (1 cm.) wide.

N. hybrida striata.—Similar to the preceding, but with more slender two-edged scapes, smaller flowers, rather less than 2 inches across, segments of a bright rose colour.

N. excellens! = *flexuosa*.—Scape two-edged, bearing large many-flowered trusses. Flowers about $2\frac{1}{2}$ inches (6 to 7 cm.) across, perianth funnel-shaped, segments $\frac{1}{4}$ inch (6 to 7 mm.) across, deep rose, with a darker coloured midrib.

N. amabilis grandiflora.—Similar to *striata* but with larger flowers, $2\frac{1}{2}$ inches across (5 to 6 cm.), segments oblanceolate, acute, bright rosy-lilac, with a deeper coloured midrib, scarcely wavy at the edge. *N. amabilis* is stated to be a hybrid between *N. pudica* and *N. humilis*.

N. flexuosa, "violet variety," has a stout two-edged scape, with bold trusses of flowers, each measuring nearly $2\frac{1}{2}$ inches across (6 to 7 cm.), segments linear oblong recurved violet, with a deep rose-coloured band in the centre, $\frac{1}{4}$ inch across (6 to 7 mm.).

N. hybrida Novelty.—A very beautiful form, with nearly regular deep rose-coloured flowers, 2 inches (5 cm.) across. Segments relatively broad, oblanceolate, recurved at the tip, scarcely or not at all wavy, 1 cm. across; midrib, of a deeper colour than the rest of the segments.

N. sarniensis carnosus.—Scape stout, markedly two-edged; scape many-flowered, perianth funnel-shaped, 2 to $2\frac{1}{2}$ inches (5 to 6 cm.) across; segments relatively broad (1 cm.), oblong recurved, glowing rose-coloured. Stamens and style slightly curved, protecting a long way beyond the segments.

N. atrorubens.—Scape stout, truss many-flowered, with relatively short pedicels (not longer than the flowers). Flowers 2 inches (5 cm.) across; perianth flattish, cup-shaped, segments oblong-acute, slightly wavy at the margins, deeply orange-scarlet. Stamens and style slightly curved, longer than the perianth.

N. Planti (? *sarniensis Planti*).—Scape two-edged, truss many-flowered, pedicels rather longer than the cup-shaped flowers; perianth, $2\frac{1}{2}$ inches across (6 to 7 cm.). Segments oblong acute, channelled, not wavy, orange-crimson; stamens and styles slightly curved, longer than the perianth segments.

N. Moorei.—Scape two-edged, truss many-flowered, pedicels rather stout, as long as the cup-shaped flowers. Perianth about 2 inches (5 cm.) across; segments oblong acute entire, 1 cm. across, rich orange-scarlet, centre of segment and midrib of the same colour. Stamens and styles nearly straight, projecting beyond the perianth.

N. Fothergilli major (*curvifolia* var. *fide*, Baker).—A noble form with a very stout two-edged scape, many-flowered trusses, pedicels stout, rather longer than the flowers. Flowers, cup-shaped, regular, 3 inches (7 cm.) across; segments broad oblong acute entire somewhat channelled, rich and glittering orange-crimson, somewhat paler in the centre. Stamens and styles curved, projecting far beyond the perianth.

N. undulata is an old friend, with slender scapes, numerous light rosy-pink flowers, in many-flowered trusses; pedicels long, slender, quite glabrous, intermixed with linear thread-like bracts. The indi-

vidual flowers measure about $1\frac{1}{2}$ inches in diameter (3 to 4 cm.). Ovaries subglobose, three-lobed, perianth-segments widely spreading, linear recurved at the tips, wavy at the margins. Filaments slender, pink; anthers small, blackish-purple, maturing before the stigma, pollen whitish.

N. pulchella [? *N. = flexuosa* var. *pulchella*] has scapes as thick as a goose-quill, trusses many-flowered. It looks like an enlarged form of *N. undulata*, with flowers about 2 inches (5 cm.) across. Segments rosy-pink, undulate, about $\frac{1}{8}$ inch (5 mm.) across.

N. humilis.—Scapes slender, flowers about $1\frac{1}{2}$ inch (3 to 4 cm.) across, irregular, segments linear-oblong, $\frac{1}{8}$ inch (4 mm. wide), recurved, rose-coloured, with a central dark rib, stamens and style curved (declinate).

N. humilis splendens has the appearance of the preceding, with the markedly irregular flowers and declinate stamens, but the flowers are much larger, and of a richer colour.

N. hybrida "Rosita".—Scape the thickness of a hen's quill. Truss many-flowered, flowers 2 inches (5 cm.) across, segments $\frac{1}{4}$ inch wide (7 to 8 mm.), linear-oblong, curved at the tip, somewhat wavy at the margins, and with a deep rose-coloured midrib.

In addition to those already named, there were sent some flowers of *N. corusca* and its variety, *N. c. compacta*, the latter a very pretty flower of brilliant tint, and closely arranged corymb; *N. elegans*, and *N. Sarniensis insignis*, with bright satiny carmine flowers.

THE SEED TRADE:

THE SEED CROPS AT HOME.—For weeks past seed-growers have been watching with considerable anxiety the signs of the weather, for they want fine sunny autumn days in which to pull up, as it were, some of the arrears of development caused by a cold and retarding spring. It is only those who are acquainted with the business that can understand what a great and important industry seed-growing is in this country, and especially in what is known as the home counties, and how a spell of fine or stormy wet weather at certain seasons of the year can make or mar the hopes and anticipations of those engaged in it. On the whole, seed-growers are having a better time in 1892 than in 1891, though by no means to the extent they could desire. Early round Peas are coming in the form of unexpectedly good samples, but quantities small, generally owing to the Pea weevil having attacked the plants in spring. Early Wrinkled varieties are also of good quality, but short in quantity also. Late Wrinkled Peas were damaged by the stormy weather, and the seeds stained, and none of English growth will be very plentiful. It is a little early to estimate the probable yield of Broad Beans, but both Long Pods and Windsors will be scarce. Essex, which is the leading Bean-growing county, has suffered much in respect of its crops, and it is said the loss to growers will be considerable, which is to be regretted. Dwarf and Runner Beans appear to be carrying beautiful crops, but much depends upon the autumnal weather. Turnips and Swedes are short in yield for the areas grown, many of the plants having been killed during the winter. Beets and Mangels have produced large crops of seeds, but the seed plants were thinned by the action of the winter, and it is some years since the Mangel and Beet plants were so heavily laden with seed, and that of good quality.

Onion seed promises to be plentiful at home and abroad, so far as the ordinary white Spanish type is concerned, which is so largely grown in Bedfordshire; the heads of seed plump, and but little blight, and, as far as can be ascertained, prices are low on the continent at present.

Parsnip is plentiful, good breadths and an abundance of produce. Carrot is particularly short in breadth, the yield of seed scarcely corresponding in breadth, but what there is promises to be of good quality. The winter killed many of the seed plants.

The foregoing are the principal vegetable seeds grown in this country, and, as far as can at present be ascertained, somewhat similar results are being experienced on the continental seed farms. *Pisum*.

NEPENTHES, THEIR CULTURE AND USE FOR DECORATION.

THESE plants are not largely grown, because they are not so readily used as many other decorative plants, but in many cases *Nepenthes* could be used for a short time, and with great effect, in the dwelling-house as single vase plants, or as suspended specimens. Of course, some of the varieties are too scarce, and some too small for this purpose, but one of the best can now be obtained for a few shillings, viz., *N. Mastersiana* ×, which can be grown to a good size in a short time under proper treatment. Of late, we have seen these plants brought into greater prominence on account of their insectivorous character, but I do not intend to advise their culture on that account, as from close observation I have made, the fewer insects they catch the longer will the pitcher remain fresh. I will give a note on feeding later on, when treating on their culture, as these plants require feeding, but at the roots rather than in the pitchers. Those who wish to see pitchers in quantity would do well to pay a visit to Messrs. Veitch's nurseries, Chelsea, where they may be seen in splendid health, and the roofs of several houses are one mass of plants covered with pitchers interesting and beautiful.

The raising of hybrids is still zealously pursued, as will be seen by the great numbers of plants round the sides of the houses, in all stages of growth, and those who are anxious to see the great strides made of late years in size of pitchers would see much to interest and instruct. In one house alone the roof for 30 feet in length is covered with grand masses of *N. Mastersiana* ×, with very fine pitchers; and as my guide said to me, it is the finest hybrid *Nepenthes* yet obtained, and here grown in great quantities, is seen its freedom of growth, with pitchers 8 to 10 inches in length, and a breadth of 2 to 3 inches, of a deep blood red, with blotches somewhat after *N. distillatoria*. It was obtained from *N. khasiana* × *N. sanguinea*. Another fine pitcher, newly introduced, is *Nepenthes Curtisii superba*, a most distinct variety; it is a free grower, and a great improvement on the original *N. Curtisii*, this variety having much larger pitchers, with more colour; the ground colour of the pitcher is a rich crimson, with yellow-green streaks; the rim is wider than the type, and more ribbed, colour deep red, the lid being much freckled. This variety should be in every collection. *N. Burkei excellens* is a grand introduction of Messrs. Veitch, from the Philippine Islands, and is the most variable variety of *Nepenthes* yet known. It differs from the type or original *Burkei* by having larger pitchers, somewhat more cylindrical, and more richly coloured; the spots on the pitchers are much larger, and deeper coloured, and the pitchers are larger and broader—a very distinct plant, of great merit. *N. Dicksoniana* × is a striking and handsome hybrid, the parents being *N. Rafflesiana*, fertilised by *N. Veitchii*; it has very large pitchers, of a light green colour, speckled and spotted with crimson. The plants are dwarfer than some varieties, and it produces its pitchers very freely. *N. Northiana* is a seedling, and one possessing great merit, the individual pitchers being 12 to 16 inches in length, and 3 to 5 inches in breadth, greenish-red, striped and spotted with crimson, its great size making it remarkable. *N. cincta* is worth notice on account of its robust habit and freedom of growth; pitchers are 9 inches long, being a pale green, with crimson and purple blotches, and is a distinct and handsome form. *N. Veitchii striata* is also a striking variety much like *N. Veitchii*, but superior, having pitchers like that variety, but deeply striped with red. Of older kinds, I merely mention a few of the most noteworthy: *N. Hookeriana* and *N. Rafflesiana* should be in all collections, they are noble pitchers; *N. sanguinea* is a beautiful kind, but rare; *N. Mor-*

FIG. 76.—SEED-CONE OF ENCEPHALARTOS ALTENSTEINII. (SEE P. 496)

ganiæ ×, a beautiful hybrid of dwarf habit; *N. Williamsii* ×, a beautiful hybrid from *N. Sedeni*; and *N. Hookeriana*, with bright red pitchers; *N. hirsuta glabrescens*, a variety with pea-green pitchers, and very distinct; *N. Chelsoni* ×, a hybrid of great merit, a free grower, and producing its pitchers freely.

Nepenthes are best grown in a moist stove, or in a house kept at 65° to 75° in the summer; some good cultivators give a higher temperature, but the minimum is most suitable for houses containing mixed plants. A bare roof may be made beautiful when devoted to this purpose; baskets made from oak-wood are the most suitable, as the air has readier access to the roots than is the case with pots, and a free circulation of it keeps the compost sweet, an essential point with plants requiring so much moisture as *Nepenthes*. Good peat in as fibrous condition as possible, with all the small or dust beaten out, with an equal portion of sphagnum, is the best compost; place a few lumps of charcoal at the bottom of the basket. Repotting usually takes place in February, after which the plants should be kept closer for a time. As soon as new growth commences, the night temperature should not fall below 70°, and during the resting or winter period, 65° is sufficient on mild nights, though 5° less in severe weather is best, as by keeping a high night temperature in winter, the plants get infested with thrips. In the growing season, syringing freely twice daily with tepid rain-water, and shading from strong sunshine, is all that is required to keep insect pests away. At Chelsea, strong measures are taken to induce the formation of large pitchers, and as it is an excellent plan to induce a fresh break at the base, I will describe it: As soon as the various growths have made five or six leaves, the tops are broken right out, which induces new breaks, and large pitchers at times; the plant if left, makes one strong growth and few pitchers, but if checked, several growths are made, producing strong plants, well furnished with pitchers. When a plant is cut down, it usually breaks from the top eye or shoot, forming an ugly growth; this should be prevented by pinching out the top break as soon as seen, which will force a break lower down the stem.

Feeding the plants in August and September with weak liquid cow-manure, at the same time giving more air, and shading less, ripens the wood, and prepares the plants for a lower winter temperature, and also prevents the pitchers shrivelling so quickly. They may at that season, and later, be used to much advantage for decoration for any special occasion. For short periods they answer admirably, but must not be allowed to remain long in cold or dry rooms. I have given various manures a trial; if not given in strong doses, a bag of soot immersed in the tank is a good plan, and keeps insects at bay. If strong manures are given they kill the sphagnum, and the plants suffer, as the sphagnum is one of their chief supports.

A few loes will suffice as to propagation: Cuttings 6 inches long should be taken, and inserted in cocoa fibre in the warm bed of a propagating box, where they root in a short time; but, of course, if the cutting is old it takes longer. A suitable cutting will root in a month or six weeks, and it should be potted up and replunged till well rooted, when it may be finally transferred to a basket. Seed is also readily raised when procurable, but unfortunately *Nepenthes* rarely flower together, so cannot be fertilised. Sown thinly in pans, and plunged in heat, kept moist, and in a temperature of from 80° to 90°, germination is effected in a month, and as the seedlings make a few leaves they should be placed in small pots, as advised for cuttings. Of course, the seedlings are longer in making large plants than those obtained from cuttings. In repotting, much care is necessary to prevent injury to the roots, as these are most delicate, and unless the whole mass of old rooting material is sour it need not be disturbed, as to do this gives a slight check. Very small baskets should be used for young plants, as excessive root space will cause the compost to become sour. With larger plants more charcoal or

a little potsherd should be used. I prefer small baskets, pans, or pots, and to rely upon moisture and feeding during the growing season; and to get abundance of pitchers, strong growth must be checked—this is readily done by cutting down and getting a break from the base. *G. Wythes*.

RUXLEY LODGE.

ABOUT one mile from Claygate Station, on the main line of the London and South-Western Railway, is situated Ruxley Lodge, the residence of Lord Foley. Around it is a fairly extensive park, and it is a very old-fashioned quiet-looking place, having no great pretensions to architectural grandeur, although it is comfortable, commodious, and a good example of the "ancient homes of England," containing a collection of pictures that many a man might envy. Its homely appearance is strengthened by the presence of many varieties of climbing plants, that during the summer months hide the lower portions of the house beneath a wealth of blossoms, varied as they are beautiful.

The flower garden in the front of the house is laid out in the orthodox manner, and has looked very gay during the summer, with a well-selected collection of the usual "bedders." *Calceolaria amplexicaulis* has been trained in the shape of pyramids in the centre of small beds, and has been much admired, although now past their best at the time of our visit. A beautiful view is to be obtained from this point over one of the most delightful portions of Surrey. On the other side is a graceful specimen of the mammoth tree, *Sequoia gigantea*, some 65 feet high, and of a more slender habit than it generally assumes. An immense Horse Chestnut, but a few yards away, has allowed its bottom branches to fall until they have reached the ground, and here they have secured themselves by freely emitting roots into the soil. The tree now forms a pleasant and uncommon archway over the path, the trunk being upon one side, and some of the rooted branches upon the other.

Entering the kitchen garden we find that it has been laid out on very undulating ground, and that, through the close proximity of tall trees, it has not the advantages one would expect to secure in a garden formed from a modern plan. Such a garden as this means a great amount of labour to "keep," to use a gardening term, but the head gardener, Mr. Jno. Miller, has had much experience, and we found a good crop of most vegetables, particularly some rows of sturdy Celery. The fruit trees in this garden have borne tolerably well this season, especially the Apples, and some Apricots that grow on the wall have done remarkably well. Some of the fruits from here secured 1st prize at the Conference at Chiswick in August.

There is also a large Orchard filled with Apples and Pears, and here there has been planted a large number of young trees during the last six years or so. Not only has Mr. Miller sought to increase the usefulness of the orchard in this way, but some few years ago a number of the older and less useful of the Apple and Pear trees were headed down, and grafted with more desirable varieties, and these have been bearing considerable quantities of fruit during the last few seasons. We do not think that this practice should be adopted in an extensive manner, however, with the idea of permanently increasing the value of the fruit quarter, but as a means of continuing the supply whilst fresh plantations are reaching their fruiting stage, there can be no doubt but the method is worthy of adoption. Of Pears and Apples there are about one hundred varieties, and we noticed that Blenheim Orange Pippin does very well here, and is a free cropper upon trees of moderate age.

Most of the glass-houses at Ruxley are like the general characteristics of the place, and are not of modern build, but they are evidently put to the best advantage, and the Vineries, Peach and Fig-houses give evidence of Mr. Miller's skill as a fruit grower. About the individual houses, and of the plants, &c., we can say little, as during our short visit no notes were taken. In the Peach-houses, however, where

the front trellis is some distance from the roof (in order that the trees on the wall at the back shall not suffer), a branch is taken from the trellis under each rafter, and attached thereto, from which some good fruits are obtained without unduly shading the other part of the trees—so says Mr. Miller. A good span-roofed house lately built, and with two divisions fitted with a centre stage, is used for the Strawberries (a good number of which are forced here), and later for Tomatos, Cucumbers, &c.

We cannot conclude this short notice of Ruxley Lodge without mentioning the excellent Mushrooms, grown in beds both inside and out—those outside on the ridge system—but most frequenters of the meetings of the Royal Horticultural Society have seen Ruxley Mushrooms.

EARTHING CELERY.

THE object in "earthing-up" Celery is to have as large a quantity as possible of the stalks in a white and edible condition. There are two means of blanching Celery—by packing the soil round it, or binding rough strong paper on to the heads, the latter answering well when it is intended to exhibit the heads, the paper preventing the outer leaves being disfigured by slugs. By this mode of blanching the Celery may be afforded liquid-manure at the root till the day it is dug up, a decided advantage over the older method of blanching with the soil. Sheets of paper are required of the breadth the Celery is likely to reach in height, from the root to the first leaves; and these should be bound neatly, but not tightly around the sticks, and in about three weeks from the time of putting the paper on them, the Celery will be sufficiently blanched for show purposes.

Some persons commence to earth-up their Celery much too soon, thus checking growth more than is desirable, the finest growth is wanted. Celery should not be earthed-up at all as long as the leaves will stand erect, but as soon as the outer ones commence to droop, the first earthing should be given it. The day previous to doing this, the soil should be thoroughly saturated if at all dry, with liquid manure if the plants are not very strong, but in some kind of soil it is a mistake to have the Celery too large, and in heavy soils very large heads decay badly during the winter. In light sandy soil it is otherwise. But even in heavy soils if there is the least suspicion that there is dryness at the root, a soaking of clean water will be an advantage. Some gardeners do not take the trouble to remove the several offshoots which spring from the base of the plants, but let all grow, not suspecting the weakening effect that these exercise on the development of the plant. All side growths should be stripped off with a sharp scotch, and the short lower leaves must also be removed. In heavy soil slugs are sure to be troublesome, and the present is the time when steps may be taken to avert this injury to the plants. With this aim, sprinkles soot and lime to which has been added a handful or two of common salt, over the soil, previously securing the Celery plants in an upright position ready for moulding up. There are several ways of accomplishing this. Some endeavour to carry this out by one person holding a Celery plant tightly together with each hand, while another shovels the soil up to them, and this is the time when the sticks are often rendered crooked by the hold on the sticks being relaxed before the soil has been made firm, small pieces of soil easily getting between the stalks and into the hearts of the plants. Again, considerable damage is done by throwing the soil against the plants in too large masses, which tends to push them over on to one side, rendering them crooked. The best method is to tie each stick with a piece of bast firm enough to prevent soil lodging in it.

In the case of tall sticks, two ties may be required, and even then it is time well spent. When all are tied, the soil at the side of the trenches must be broken quite fine before placing it about the plants, to which it should be thrown or rather pushed, as high as the centre leaves are visible. Press the soil firmly about the plants, and when all is

complete, the leaves require to be released, which is best done by cutting the bast, and allowing it to remain in the soil. After an earthing-up is completed if it is not the final one, sufficient soil should be dug out of the trench to suffice for another earthing-up, and this should be laid in the rough on the outer edge of the moulding, where it will get pulverised by rain and wind, and in a fit condition for the next earthing-up, say in fourteen or twenty-one days. When the final earthing takes place, the sides should be made quite smooth; a sharp pitch should be given the ridge at the top so that rain will readily run off. S. H.

BOOK NOTICE.

LANDSCAPE GARDENING.

WE were recently made aware by the startling details of Messrs. Blomfield and Thomas' book on *The Formal Garden in England* [See *Gard. Chron.* 1892, p. 276, Vol. XI.], that the battle of opinions as to the art of landscape gardening still rages in some circles with all the old shifting reasons; and now we are confronted with a contribution to the imbroglia by Mr. W. Robinson,* whose expletives and adjectives are scattered about as they were wont to be in our grandfathers' literary feuds. Two books (*Formal Garden* and *Garden Craft*) are "not worth notice for their own sake," yet a book is written about them! "Mr. Blomfield writes nonsense, and then attributes it to me;" "a passage full of nonsense;" "confusing art drive!" and so on. In one passage this eternal truth is given prominence: "How much better it would be for every art if it were impossible for men to write about things of which, by their own showing, they have not even elementary knowledge!"

To criticise a criticism usually carries the writer into the airiest regions of mere opinion. Yet that is in some sort the task we set ourselves; but we do not propose to discharge our duty on such shifty lines. We may, however, tread safer ground, if we examine some of the reasons which Mr. Robinson adduces for his generally condemnatory remarks on Messrs. Blomfield and Thomas' book, and, if we can, discover the bases of some of his actions. We have already recorded our opinion on the work with its strange and extreme reasoning, and of course we have many points of agreement with Mr. Robinson's strictures and opinions, which must be common to many readers who have artistic knowledge and feeling, and who are sensitive to mis-statements, whether resulting from ignorance or defective appreciation. With many of the conclusions reached we cordially agree, although reaching the goal not always by the same path. Here, then, we have Mr. Robinson as self-appointed judge, and we are concerned with the utterances that come from the critical judgment-seat.

The judge thinks the frequent presence of "stupid work in landscape gardening" almost excuses the appearance of the two books, although he concedes that "The one English thing that has touched the heart of the world is the English garden." Though not just in this order, Mr. Robinson, after mercilessly showing up many passages in the book he is criticising, very properly objects to the use by its authors of the coined term, "Landscape" (Heu!), which is used throughout the book as "a term of contempt," and then in the following passage comes near to one of the main portions of the endless dispute: "They may be quite sure that there is a true and beautiful art of landscape gardening, notwithstanding their denunciations, and it is none the less real because there is no neat definition of it that pleases the minds of those who declare that it does not exist." This is one of the standards round which the battle rages. Why does not Mr. Robinson contribute his

own definition, if he has one? There are definitions, and here is the latest, which may well be quoted, even if, or perhaps because, Mr. Robinson may not have seen it. Mr. Milner, in his book on the *Art and Practice of Landscape Gardening*, says,

FIG. 77.—POLLEN CONE OF ENCEPHALARTOS ALTENSTEINII. REAL SIZE. (SEE P. 496).

"It is the province of the landscape gardener, as I understand the art, to appreciate the multitudinous means whereby Nature expresses her beauty, and so to use those means artistically as to arrange their force for producing the delightful result he desires to achieve. To servilely copy Nature's forms is to incur

the pettiness of mere reproduction in little, with the penalty of a falsification. To utilise her means, and to let the spirit of her works influence our art in every practicable way, is the true practice of the art of landscape gardening." If this definition is not "neat" enough, it at least affords a reply to some of the most hackneyed assertions bandied in the current dispute; and particularly what Mr. Robinson styles "the nonsense" of Mr. Blomfield. "We go to Claude, and having saturated our minds with his rocks and trees, we return to Nature, and try to worry her into a resemblance to Claude." This is indeed an astounding description of the art, not based on the intellectual rock, and very innocent of prevalent knowledge.

Mr. Robinson seems to have a contemptuous opinion of our architecture. "In these days, when our ways of building are the laughing-stock of all who care for beautiful buildings, there is plenty for the architect to do without spoiling our gardens; most of the houses built in our time are so bad that even the best gardening could hardly secure them from contempt." These are remarkable phrases when applied to the works of Norman Shaw, Aston Webb, Bodley, Waterhouse, Burgess, Jackson, and others. But they seem to consort with his opinions of the landscape gardeners, all except one, whose pose is more than once noticed in this book.

The best landscape gardening of the present day does not practise in either extreme of the opinions that are so much agitated. It takes a middle course with a due regard to appropriateness, an element somewhat under-estimated by Mr. Robinson. In regard to the terrace, for instance, that feature is used as a base for the house, to give dignity and an expression of stability to the structure, and its architectural details are so used as to accord with, or even to extend the art expression of what is, indeed, the principal object in the whole demesne. In connection with the terrace, formal gardening is properly used, and is characterised by the beautiful natural forms that the horticulturist's enterprise has placed at our disposal. From the terrace the garden is treated by gradations to merge into those wider expressions of natural beauty that we style the park, and so on to the distant landscape, whether there to our use, or partly or wholly created by artistic treatment. Mr. Robinson would bring the field up to the house wall without intervention of formal feature at all. Messrs. Blomfield and Thomas would circumscribe the house with a space closed by high walls shutting out the landscape picture, and letting their formal garden blossom principally with antiquarian fade! *Medio tutissimus ibis.*

ROUND LIVERPOOL.

(Continued from p. 462.)

HIGHFIELD.—In the compact gardens surrounding the residence of William H. Tate, Esq., the whole range of gardening, both indoors and out, in more or less degree in the several departments, is admirably carried out by Mr. Haigh, the gardener at Highfield; or, rather, by the co-operation of the proprietor and his gardener, after the manner which we always find where gardening is successful.

The plant-houses at the present season are the most attractive part of the garden, and in them we found a fine lot of plants, and especially those useful for decoration or for cutting. Among them, bulbous plants are prominent, and *Eucharis*, *Pancratium* (or *Hymenocallis*, as they more properly should be called), *Griffinias*, &c., are well and extensively grown.

Roses, both indoors and out, also come in for a good share of attention, and *Crotons*, *Dracenas*, &c., are produced in neat well-coloured plants, a stage which, while giving really useful plants, represents them in a far better aspect than the unwieldy specimens sometimes seen in gardens.

The Orchids, which are special favourites at Highfield, on account of their giving their gorgeous blooms at all seasons, and especially when showy flowers are scarce, are excellently well grown by Mr. Haigh, and the showier species are those mainly embraced in the

* *Garden Design and Architect's Gardens*. Two reviews, illustrated, to show by active examples from British gardens that clipping and aligning trees to make them harmonise with architecture is barbarous, needless, and inartistic. By W. Robinson, F.L.S. (London: John Murray, 1892.)

collection. The varieties of *Cattleya aurea* are grown in goodly number, and the beauty of the many flowers at present open in the houses in which they are suspended, renders an excuse for partiality to them needless. This beautiful section of *Cattleyas* has been largely increased in variety lately by the recent importations, most of which are readily distinguishable to those who know them. The variety called *C. chrysotoxa*, imported by Messrs. F. Sander & Co., is much liked at Ighfield, and even this variety has a great range of sub-varieties, for some have white sepals and petals, and in others, the labellum nearly approaches that of *C. Hardyana*. *C. Warszewiczii*, or, as it is more commonly called, *C. gigas*, does well at Highfield, and the intermediate form between it and *C. aurea*, viz., *C. Hardyana*, also there finds a place. Glancing through the Orchid-houses, in which good culture is evident, we note a very fine lot of *Cypripediums*, large sturdy plants; a remarkably well-grown lot of *Dendrobiums*, and especially of *D. Wardianum*, *D. nobile*, and other showy kinds; a good batch of *Miltonia Roezlii* and *M. vexillaria*; *Vanda cœrulea*, well grown, and well bloomed; *Odontoglossum crispum*, and other cool Orchids, clean, sturdy and floriferous; and the other species usually met with, in excellent trim. But, passing down the fruit range, we come to one of the best and most satisfactory features in the garden, viz., the collection of Mexican *Lælias*, which are suspended from the roof of the Fig-house, and of the condition of these too much cannot be said. The varieties of *Lælia anceps*, both white and coloured, are sending up flower-spikes very profusely, and, shortly, there will be something like one hundred and twenty of them in bloom, which, with the flowers borne on the stout spikes of *Lælia autumnalis atropurpurea*, and other species, will make a fine and lasting show.

Another fine specialty here are the magnificent plants of *Lælia purpurata*, which thrive equally as well as the *L. anceps*; and in the same range of Orchid-houses are a grand lot of *Cœlogyne cristata*, a fine one of *Odontoglossum grande* in flower, and good *Oncidium tigrinum*, *O. macranthum*, &c. In another little house, on a shelf, are a row of *Dendrobium Jamesianum*, in excellent condition; and in the pretty little fernery, the specimen of *Adiantum Williamsii* is, perhaps, equal to the best plant of it ever grown; and other good specimen Ferns, too, are here, quite worthy to keep it company.

FRINGILLA, SEFTON PARK.—There is a red-letter day now and then in every garden where Orchids are made the special or only feature, and on such a day did we pay a visit to Reginald Young, Esq., one of the most enthusiastic cultivators of Orchids in the Liverpool district. The reason why the day should be marked was soon disclosed to us, by our being presented to the loveliest plant of *Cattleya Hardyana* we had ever seen, and which, although only a moderate-sized plant, bore several spikes, bearing altogether ten of its gorgeous flowers, the greater part of which had only opened that morning. Viewed in comparison with the original *C. Hardyana*, Mr. Young's may be said to be lighter, and with a more pronounced marbling of cream colour showing through the rosy-crimson surface colour of the sepals and petals, but *C. Hardyana* it is, and, moreover, a form which does credit to the type. The class of *Cattleyas* to which this beauty belongs, viz., *C. Warszewiczii*, *C. aurea*, &c., do remarkably well in the neat Orchid-houses at Fringilla, under the watchful care of Mr. Poyntz, the gardener. A few of them are now in flower, and we readily call to mind the bloom of one of the plants recently sent to us, and which measured over 9 inches across, and had a most extraordinary development of the richly-coloured labellum. Another there now in bloom appears to be a distinct type, the flowers being light in colour, and the yellow blotch formed on each side of the lip of the ordinary type being in this one white.

Cypripediums are great favourites here, and the fine collection of them has many still in bloom, and notably the many good forms of *C. Ashburtoniæ* × *C. Harriianum* ×, and that favourite, *C. cananthum*

superbum ×. Passing through the houses we find them bright with the flowers of *Vanda Kimballiana*, *Lælia pumila Dayana*, *Cattleya guttata*, *C. velutina*, *Dendrobium Dearei*, and other *Dendrobiums*, *Phajus maculatus*, *Cœlogyne speciosa*, *Restrepia antennifera*, *Zygopetalums*, &c., and soon there will be a fine show on the plants of *Epidendrum vitellinum majus*, which between them are sending up about eighty spikes; *Lælia anceps*, *Cattleya Bowringiana*, and other autumn and winter-flowering species.

(To be continued.)

BRITISH FUNGI.*

WE are pleased to announce the commencement of the publication of a new work on British fungi, which proposes to do for these peculiar plants what Cooke's *Handbook of British Fungi* did for them twenty-one years ago; that is, consolidate all the species in one work, and give description of all the known British genera and species up to date, with illustrations of the several genera. The *Handbook* has been so long out of print, and the number of recorded species has so much increased, that the need of such a book has long made itself felt, apart from all the modifications and limitations of genera, and other improvements suggested by the advancement of science, and better methods of study. The work in question is proposed to occupy three volumes, of which the first is published. We fear the author is far too sanguine in his hopes of comprising all the species within the limits of three such volumes. This first includes a portion only of the Basidiomycetes, commencing with the *Gastromycetes*, and working backwards through the latter position of the *Hymenomycetes*, of the *Handbook*, to the commencement of *Agaricini*. We confess our inability to appreciate the grave reasons which induced our author to depart from the orthodox sequence, and invert the order of succession. Without some good reason, which does not appear upon the surface, we submit that such a departure is an error of judgment, inasmuch as it tends to the confusion of students, and increases the difficulty of referring back to, and comparison with, previous authors, without any corresponding advantage.

The book is neatly and clearly printed, and the cuts sufficient for the purpose, whilst the characters of genera and species seem to be all that could be desired, not prolix, but ample and "up to date;" including spore measurements, which is a somewhat recent innovation, liable to abuse in practice, if applied too inflexibly.

The best test of a work of this nature lies in its practical use, and we doubt not that experience will confirm our impression that it is workmanlike in character, and careful in execution, although we had rather not have had occasion to express dissent from the method of arrangement, or taken exception to the elevation of the subgenera of *Agricus*, to the rank of genera. We cannot conclude this brief notice without a special commendation of the fullness of the descriptions, and illustrative notes, under each species. It is clearly manifest throughout, that our author is in sympathy with the student, and is doing his best to give him all the help he can in the discrimination of species. The study of fungi has somewhat declined of late in this country, and British mycologists, ever few in number, have sensibly diminished; but we hope that these volumes, when completed, will inaugurate a new era of activity, and revive once more a useful and interesting study. M. C. C.

THE WEEK'S WORK.

FRUITS UNDER GLASS.

By J. RIDDELL, Gardener, Castle Howard, York.

PEACH AND NECTARINE TREES.—Prune, clean, and retie all trees which have shed their leaves. Vines and Figs may be put off till a more convenient

* *British Fungus Flora: a classified text book of Mycology.* By George Masee, in 3 vols. Vol. I. (Bell & Sons.)

time, but if Peaches and Nectarines be left till, say, the early spring-time, their buds, which are then more or less on the move, run the risk of getting thinned in numbers if much cleaning has to be done; therefore, it is desirable that all operations involving the manipulation of the shoots should be carried out at the present season. In some instances the thinning out of the bearing shoots to from 4 to 6 inches apart is all that will be necessary in the way of pruning, and while doing this the aim of the pruner should be to remove as much of the old wood as possible, and reserve the young at about an equal space apart. Recently-planted trees, however, will often be found with shoots which have not perfectly ripened, the points being green, and these should be shortened to a stout wood bud on a ripened part of shoot. Scale and red-spider are the chief insect enemies of the Peach. If these were present during the summer months an effort should be made to get the trees into a clean start at this season. For scale use a stiff brush and Fir-tree oil at its recommended strength, going over every twig and branch, and apply two syringings of the same insecticide at intervals of a fortnight afterwards. If this cleaning be well done, none of the pests referred to will escape. I treated a house in this manner last winter with excellent results. Of course, the woodwork, trellises, walls, &c., had the benefit of a syringing, the walls being also carefully lime-washed, the wash having a handful of flowers-of-sulphur mixed into it. After the trees have been fastened to the trellis, and the house properly cleaned, remove the soil of the border to the depth of 3 inches, which will tend further to keep the trees clean, by removing any insects or insect eggs which may have fallen on it, and cover the roots with fresh materials. Old trees may be supplied with a compost which contains a liberal sprinkling of lime and basic slag. In fact, it will be prudent in some cases to more thoroughly overhaul the border, and afford the plants a chance of becoming robust. Good fibry loam will, nevertheless, be all that will be required by young trees, excepting that the lime formerly supplied to the soil may have become lost by watering, and found its way to the subsoil or lower parts of the border, and another application of it becomes indispensable. Afford the borders on the completion of the job a thorough watering, but at no time in the winter months should Peach borders become dry, or bud dropping will follow. All the same, watering can be overdone if the drainage is not good, and the gardener must ascertain by examination if the soil needs much or little water. Keep the houses cool and airy, 3° or 4° of frost will do no harm to the plants.

THE ORCHID HOUSES.

By H. A. BURBERRY, Orchid Grower, Highbury, Birmingham.

REMARKS AND HINTS ON CULTURE.—Now that little repotting or top-dressing remains to be done, and not much time is taken up in watering the plants, it will be found a good time for a general clearing up of each house in succession, washing and freeing the plants from dirt, scale, thrips, and other insects. In the performance of this sort of work, an insecticide, into which each plant should be dipped, should be at hand. After, the leaves and bulbs should be wiped with a sponge, to remove the wash, and prevent it being carried to the roots. Some well-tried and safe insecticide should be used which will not injure the tenderest plant, whilst it should be capable of destroying thrips and aphids, and of making scale readily removable. Instructions for making a good solution were given in the Calendar for the week ending February 20. Many of the insecticides that are sold for the same purpose, are efficacious when diluted with rain-water to the desired strength, but if the grower has not used them as yet, I would advise him to try the effect of a washing on one of the plants before using it generally. Cockroaches and woodlice will be troublesome if not destroyed at this season. The first-named are easily killed-off by using a certain preparation sold for this purpose, and the others may be trapped in several ways, one of the best of which is, I think, to hollow out a Potato or a Carrot, and place it concave-side downwards on the surface of the compost in which the plant is growing; and it is likewise a capital trap for slugs, snails, and centipedes, which are so destructive to tender flower-spikes, especially in the cool-house. When cleaning the plants, remove all such growths of sphagnum moss which are overgrowing the pseudobulbs, hiding them from view, and excluding light and air from them to the detriment of the plant. The woodwork, glass-staging,

and walls, should be well cleaned, and all places likely to harbour insects cleared out.

TEMPERATURES.—For the *Odontoglossum*-house 50° is a good night-temperature, and 55° or 60° will be suitable by day, a fair amount of air and moisture being afforded. I would advise Orchid-growers not to go to extremes with either air or moisture, but have due regard to the state of the weather, and to be careful in watering any plant, as none will continue healthy if this be overdone. The warmth of the intermediate-house and that for the *Masdevallias* should not exceed 55° at night, or 60° to 65° by day. It is well not to let the temperature of the *Cattleya* and Mexican-houses get too low, many plants not having yet matured their pseudobulbs; 58° by night, with a rise of 10° by day, will answer very well for the present, with a plentiful amount of air on suitable occasions. For the East India-house, a temperature of 65° by night, with a rise of 10° by day, will suffice, taking care to keep those plants that require most heat at the warmer part of it.

THE FLOWER GARDEN.

By H. W. WARD, Gardener, Longford Castle, Salisbury.

PREPARING THE GROUND FOR PLANTING ROSES.—The soil most suitable for the Rose is a rich loam, inclining to be heavy, of good depth, and resting on gravel, and if the land slopes to the south-east or south-west all the better. Should the natural soil be too light, some clay should be well mixed with it. On the other hand, should it be unduly stiff and impervious to water, leaf-mould, road-grit, coal-ashes, burnt-earth, and short manure, should be added to it, and well mixed with it in trenching the beds. As a rule, it may be said that Wheat-land will grow Roses well, their cultural requirements being properly attended to.

PLANTING.—Although Roses may be planted at any time in the interval between the beginning of the month of November to the end of February (weather permitting), the sooner the work can be done in November or December the better will be the results the first year. If the Roses are planted in rows, as, for instance, at the sides of the walks in the garden, holes of about 18 inches in diameter and depth, should be dug out, and, if necessary, a layer a few inches deep of hard materials put in as drainage. If the excavated soil is unsuitable, replace it with one consisting of three-parts good loam, and one of rotted manure. This being well mixed, plant the Rose bushes, trees, or standards, in the centre of each hole, and at about the same depth as they stood before, treading the soil well about them. Before planting, cut off any damaged or unduly long roots with a knife, and in such a manner that when the plant is put upright the cut surfaces will press on the soil. This done, put a stout stake to each plant, and secure the Rose to this with a loose band, and afterwards afford a mulch, 2 inches thick, of rotted manure. Choose a fine day for the planting, and never plant when the ground is sticky, but lay in the plants, and wait till it is drier and workable. Roses growing in beds, as well as those freshly planted, should at this season have a surface-dressing of manure.

ROSES ON THEIR OWN ROOTS.—For planting in beds I prefer own root Roses put in about 4 feet apart, if the plants are strong, pegging the shoots over the beds at the end of the following March or early in April, according as the season and situation are early or late. Thus treated, the shoots send out flower-bearing side shoots over nearly their entire length, and the suckers, which annually push from the roots, get duly pegged down between the older shoots, which ultimately, i.e., when the allotted space has been properly covered, they will replace, the old growths being cut out each year as soon as the bloom is over. In this way fresh vigour, and its consequent floriferousness, are given to the plants. In my next Calendar will be found a list of varieties.

WINTERING ECHEVERIA SECUNDA GLAUCA.—Plants of *Echeveria* should now be taken up, the offsets or young plants being removed and "sized," should be stored away in shallow boxes, putting all the large, medium, and small-sized plants in boxes by themselves, working light mould firmly about the root stems, and then standing the boxes in any cold house or pit where a little protection can be afforded from frost. If necessary to extend the stock, the root stems of the old plants should be reduced, and then be stored away in boxes as described above.

THE KITCHEN GARDEN.

By G. WYTHES, Gardener, Syon House, Brentford.

POTTING-UP CAULIFLOWER PLANTS.—Cauliflowers should now be potted in 48's or large 60's for early spring planting. It is an old method of preserving them over the winter, but it is a trustworthy one. When these plants are pricked-out into frames, the growth gets before planting-time somewhat drawn, and a check is given them when transplanted; whereas in pot-growth it is sturdier, and the plants can often be kept more exposed to the air. The larger-sized pot admitting of the plants attaining a good size without cramping the roots or straining them, and when they are potted plunge in coal-ashes for a few weeks before sheltering them, it does them much good. Damp is the chief thing to guard against, therefore heavy rain should not fall on the plants during cold weather; rich soil should not be used, or light potting. Two excellent varieties are the Pearl and the old Walcheren. Early London is a variety often recommended, but it is no earlier than the first-named, and is a looser-growing plant with long leaves. If handglasses can be spared (nine to a full-sized light), may yet be planted out on a warm border, reducing the numbers at planting time to the corner plant.

ASPARAGUS BEDS.—The seed-bearing stems now ripe should be carefully cut off before the seed falls, otherwise the immense number of self-sown plants on the beds will greatly impoverish the permanent plants. The haulm which is not bearing seed should remain till it is quite ripe, too early removal causing loss of vigour. Plants required for forcing should have their stems cut off. When Asparagus does not succeed in the staple soil, the present is a good time to prepare materials for beds, as when this is done a few months before planting or sowing, these become consolidated, and in better condition for either purpose.

RHUBARB.—This is much required towards the end of the year, and those who cannot afford space for forcing the roots out-of-doors should lift the roots when the foliage is ripe, and place them close together in a shed before beginning to force, the lifting causing them to respond quickly to forcing. To get early Rhubarb, a brisk bottom-heat is required if the roots are dug up and placed in the forcing-house, but less under the preparatory method. The Rhubarb quarter should have all decaying leaves cleared off, and the crowns exposed so as to mature them; and in lifting roots those should be selected which have been undisturbed for two or three years. There is much difference in the time at which the different varieties come into use, and for forcing an early kind only should be selected, as Royal Albert, Myatt's Linnæus, or Johnston's St. Martin; the last is an excellent forcer.

ROOT STORES.—There should be no delay in getting the various root-crops requiring protection into store, and, if possible, when they are dry. Onions and Potatoes will require frequent examination, and turning over. A good method of keeping Onions is to rope or tie the bulbs in bunches. This may be done in bad weather, when the gardeners cannot work out-of-doors. Keep the bulbs as cool as possible. Beans and Peas, and other seeds should be cleaned, and placed in a dry, cool store, and properly labelled.

THE HARDY FRUIT GARDEN.

By H. MARKHAM, Gardener, Mereworth Castle, Maidstone.

ROOT PRUNING.—This is a matter the gardener must give careful consideration to when it is decided to lift and prune the roots of any tree or bush that may not be doing well. The work should be taken in hand and completed before the season of planting generally begins. If the trees to be root-pruned are large, only one-half of the mass of roots should be dealt with in one year. When lifting the roots, begin by opening out a wide trench so far away from the stem as the branches extend, and take out the soil from this trench at the least 2 feet in depth, and when this is cleared of soil, undermine the body of roots, constantly throwing the soil back, taking great care to lift or sever every root that has a downward course. Having got out all the roots intended to be lifted this time, and as near to the stem as it is prudent to go, mat them over, or cover with damp litter, whilst the operation of smoothing the bruised and mutilated root-ends, and the shortening of long-reaching ones, and those pointing downwards, is in progress. Having completed this kind of work, first make

a firm level platform for the lowest stratum of roots to rest upon; spread these out in radiating lines, using wooden pegs to keep the more stubborn in position, and then cover them with a few inches of soil, and treat the next stratum in the same manner, always making the soil very firm about the roots; and proceed thus till the topmost roots are placed under the soil, which should cover these last to a depth of 4 inches. Peaches, Plums, Pears, &c., may all be lifted and transplanted at this season, even if they are of large size, without fear of next year's crop suffering, if the work be done carefully and early. Young trees growing rapidly, and where there is plenty of wall space to cover, should not be root pruned before the space is covered, as the trees do not fruit naturally whilst growing fast. The trees may then be lifted or root pruned. All preparations for planting young nursery trees should now be made, and the required trees sent for. Gather Apples and Pears when dry, and examine those in store, removing decayed fruits. Keep the fruit-room cool. Many of the best varieties of Pears will now be ripe, and the riper specimens should be selected for consumption. The following are excellent at this season, Doyenné du Comice, Marie Louise, Thompson, Emile de Heyst, Beurré Superfin, but unfortunately they ripen nearly at the same time. Winter Nelis, a not large but a delicious fruit, should not be overlooked when ordering trees, and others are Durondeau, Glou Morceau, Passe Colmar, and Olivier de Serres.

PLANTS UNDER GLASS.

By R. MILNER, Gardener, Penrice Castle, Swansea.

VIOLETS.—There should be no delay in making up frames or pits for winter Violets, and getting them planted. The pit or frame should be filled up to within 12 inches of the glass with fairly rich light soil, made firm beneath and around the plants, and when lifting these, preserve as far as possible the ball intact, and compact. In planting, allow 6 to 9 inches between the plants, according to strength of growth of the variety, close planting resulting in a poor crop of flowers. Till the plants are established in the soil, a light shade should be afforded them during bright sunshine, and slight overhead sprinkling early in the afternoon, which will favour the emission of fresh roots. After this has taken place, air should be admitted to the frame whenever it does not freeze between 8.30 A.M. and 3.30 P.M. In mild weather the plants are benefited by a slight amount of ventilation all night.

CHRYSANTHEMUMS.—After this date it will not be safe to let the plants stand out-of-doors, and steps must be taken to find space for them in a light house, where they will be safe from frost, and will not suffer from dampness. Ainery or Peach-house from which the crop is taken are suitable places. The glass should be cleaned, so that there is no obstruction to the light, and all decaying substances cleared out of the house. See that the drainage of every plant is efficient, and that all dirt and decayed leaves are removed, washing the pots, and slightly surfacing with fine loam if the space at the top will allow of it; and should the least sign of mildew present itself, apply flowers-of-sulphur at once to the affected parts. In staging, keep the heads of the plants near the roof, and allow ample space between the plants. During fine weather, allow the ventilators to be left open night and day, the hot-water pipes being made slightly warm, so as to promote the circulation of air amongst the plants, thus preventing damp affecting the flowers.

HERBACEOUS CALCEOLARIAS.—Plants which are still in small pots should be potted into others slightly larger; and as Calceolarias are very impatient of fire-heat, they should be placed in a frame or pit, where there is just sufficient heat to keep out frost. In the southern parts of the country a banked-up garden-frame and mats are all that will be required to carry the plants through the winter.

BULBS.—The early-flowering species of Lilies should now be potted when received, for if left out of the soil for long periods of time they become weakened, and bring poor blossoms. Bulbs which were flowered in pots will now be on the move, and should be repotted, and placed in a cold frame or pit with the other bulbs. If not already done, all bulbs of Hyacinths, Tulips, Scillas, Polyanthus, and paper-white Narcissus, should be potted forthwith, also Frezias refracta alba to form a succession to those started several weeks previously.

EDITORIAL NOTICES.

LETTERS FOR PUBLICATION.—All communications intended for publication, as well as specimens and plants for naming, should be addressed to the Editor, 41, Wellington Street, Covent Garden, London. Communications should be WRITTEN ON ONE SIDE ONLY OF THE PAPER, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

PLANTS, &c., TO BE NAMED.—Correspondents sending plants or fruits to be named, or asking questions demanding time and research for their solution, must not expect to obtain an answer to their enquiries in the current week. Specimens should be carefully packed and numbered, and not more than six should be sent at one time.

LOCAL NEWS.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

ILLUSTRATIONS.—Photographs or drawings, suitable for reproduction in these pages, of gardens, or of remarkable plants, flowers, trees, &c., are particularly solicited.

NEWSPAPERS.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

Advertisements should not be sent to the Editor, but to the Publisher.

APPOINTMENTS FOR THE ENSUING WEEK.

SALES.

MONDAY,	OCT. 24	Sale of Plants and Dutch Bulbs, at Protheroe & Morris' Rooms.
TUESDAY,	OCT. 25	Sale of Nursery Stock, at Neale's Nursery, Wandsworth Common (two days). Sale of Dutch Bulbs and Imported Orchids at Protheroe & Morris' Rooms.
WEDNESDAY,	OCT. 26	Dutch Bulbs, &c., at Stevens' Rooms. Fruit Trees, at Horne's Nursery, Cliffe, near Rochester. Established Orchids, at Seeger & Tropp's Nursery, East Dulwich, by Protheroe & Morris. Dutch Bulbs at Protheroe & Morris' Rooms.
THURSDAY,	OCT. 27	Nursery Stock, at Tangley Park Nurseries, Hampton. Nursery Stock, at Hollamby's Nurseries, Groombridge, Tunbridge Wells (two days), by Protheroe & Morris. Dutch Bulbs, &c., at Sale Rooms. Orchids of the late T. Harcourt Powell, Esq., at Stevens' Sale Rooms.
FRIDAY,	OCT. 28	Sales of imported Orchids and Dutch Bulbs at Protheroe & Morris' Rooms.
SATURDAY,	OCT. 29	Sale of Dutch Bulbs at Protheroe & Morris' Rooms.

CORRECTED AVERAGE TEMPERATURE FOR THE ENSUING WEEK, DEDUCED FROM THE OBSERVATIONS OF FORTY-THREE YEARS, AT CHISWICK.—47°·3.

Cycads at Kew.

THE collection of Cycadeous plants in cultivation at Kew stands unrivalled, both in regard to the number of species represented, and the size of the specimens generally. The group represented in our Supplementary Illustration is made up of huge specimens of *Encephalartos*, *Dioon*, *Cycas*, *Macrozamia*, and *Zamia*. These, however, are only a portion of the Cycads contained in the Palm-house, very large specimens occurring frequently among the several large groups into which the giants of the house are now divided. *Cycas circinalis*, 9 feet high, and branched, is planted out in one of the beds among great Palms and Musas; a male plant of *C. revoluta*, with a magnificent rosette of leaves, is conspicuous in the north end of the house, and last year attracted considerable attention whilst bearing a cone 16 inches long. Cycads generally fruit well at Kew, and there is now in Museum No. 1 a large collection of the cones of these

plants, most of which have been produced by the Kew plants.

The ornamental character of almost all Cycads is made abundantly evident by those in cultivation at Kew. For large stoves or warm conservatories many of them are at least as well adapted as the best of Palms and Tree Ferns. A large house planted with the best of these three orders might be made a magnificent picture, full of interest and charm for the scientific as well as for the everyday person. The two which may be called fairly well-known garden plants, viz., *Cycas revoluta* and *C. circinalis*, have not a few rivals in decorative value, such being *Zamia muricata*, *Z. Lindenii*, *Encephalartos Hildebrandtii*, *E. Frederici-Guilielmi*, *Ceratozamia mexicana*, *Macrozamia Hopei* and *M. Macleayi*. There are also some beautiful species of *Cycas* beside the two common ones. There are few plants more interesting and ornamental than the anomalous *Bowenia spectabilis*, and in the whole range of garden plants we have nothing nobler than *Encephalartos Altensteinii*, when largely developed, as it is at Kew (see figs. 75, 76, and 77).

The cones of many Cycads are highly ornamental, both in form and colour, whilst some are of great size. *Encephalartos villosus* produces cones 18 inches high, and 6 inches wide, formed like a Pine-apple, and coloured bright yellow on the fleshy scales, through which the large nut-like seeds, coloured rich red, are finally partially exposed. The collection of cones sent from Kew to illustrate Mr. CARRUTHERS' lecture before the Royal Horticultural Society on Tuesday last excited as much admiration as surprise among cultivators, many of whom, forgetting how many had been illustrated in our own columns, could not understand how such things could be in English gardens, and they not know of them.

Although Cycads are rare in the garden, many of them are old introductions. According to the Kew records of J. SMITH, *Cycas circinalis* was in cultivation there in 1700, and it is at least a hundred years since *C. revoluta* was introduced. The first plant of *Encephalartos Caffer* sent by MASSON to Kew in 1775, and which Sir JOSEPH BANKS saw in cone in 1819, is, we learn, alive and well at Kew still, as also are the six plants of the same genus, which were received from the Cape in 1849. JAMES BOWIE sent *E. horridus* to Kew in 1823, and his plants are thriving in the Palm-house now.

The recent additions are *Macrozamia Moorei*, received in 1882 from Australia, and several other species of this genus, among them being *M. Dyeri*, named in compliment to the Director of Kew, who has long paid special attention to Cycads, with a view to writing a monograph of them, having accumulated splendid material for that purpose. *Zamia Houtteana*, a broad-leaved distinct species; and *Dioon spinulosum*, a handsomer plant than *D. edule*, are other striking Cycads of recent discovery, and now represented by living examples at Kew.

The cultural requirements of Cycads formed the subject of an interesting and useful article published in the *Gardeners' Chronicle* on March 9, 1889, p. 298, from the pen of Mr. FRANK ROSS, whose experience at Kew and at Pendell Court made him acquainted with the requirements of these plants.

Importations of the stems of Cycads are not unknown to London auction rooms, and they sell cheaply enough. There need not be any fear as to the health of these imported plants; at any rate, those obtained in this way for Kew have, as we are informed, proved successes.

The most extensive collection of Cycads in

this country is in the possession of Mr. BULL, at Chelsea, who has introduced not a few of the best of them, and who has long since proved himself a successful grower and a keen admirer of Cycads generally. Some of Mr. BULL's plants have from time to time figured in our columns; but for all that, the gardening public is hardly aware of the grand subjects at their disposal. It is far otherwise on the continent. There are good collections of these plants in the Botanical Gardens of St. Petersburg, Hanover, and Berlin. Visitors to Ghent, especially at the quinquennials, are generally struck with the magnificence of these plants. Many of them are highly ornamental, even when small, as was illustrated on Tuesday by Messrs. SHUTTLEWORTH, but we were surprised to learn from Mr. WILLS that the plants are not suitable for room-decoration. Mr. CARRUTHERS' lecture, mention of which is made in another column, was well illustrated by foliage and cones from Kew. It was an admirable summary of many of the chief points of interest in this most interesting group.

The Opening of Kew Gardens.

THE agitation to secure to the general public the opening of Kew Gardens at an earlier hour than at present is one that would have

our hearty sympathy did we not know, on the one hand, that the class of persons for whom the boon is sought is the one least worthy of consideration in the matter; and, in the next place, that every reasonable facility is already given to gardeners and those who have business in the gardens as distinguished from mere sight-seeing or recreation. It is for the officers of the establishment to decide whether or not the public could be admitted at an earlier hour than at present to certain portions only of the garden without prejudice to the work of the establishment and the requirements of the students. If they say that these—the main objects for which the garden exists—cannot be met unless the public is excluded till 12 o'clock from every part of the garden, then undoubtedly the public ought to be so excluded. We believe it to be a fact, that no casual visitor who makes application at the office is ever excluded if he can show that he is a gardener, an artist, a botanist, or a student in any department of horticulture and botany desirous of using the garden. Those who study regularly in the garden are provided with tickets on application, and they have facilities for comparing, examining, and drawing specimens, which could not possibly be granted, or if granted, exercised, during the public hours. There are at present, we believe, about 1000 such ticket-holders.

The only element practically excluded, then, is the "nursemaid and children" element, and their presence in a botanic garden is hardly desirable at any time, much less so when serious work is going on. The majority of the residents in the neighbourhood, or of visitors from a distance, do not care, or are not able, to visit the garden in the forenoon. Those whose only object is recreation are already well provided for; no persons are so well supplied with recreation grounds and walks as the fortunate residents at Richmond or Kew. As we have already pointed out, there are dozens of parks, but there is but one Kew. To deprive the gardeners and the students of their privileges would be to inflict a serious damage to horticulture, whilst to reduce Kew to the level of an ordinary place of recreation, would not only cause inconvenience to students, but entail a calamity on the whole empire.

W. H. WOODS

W. H. WOODS

CYCADS IN THE PALM HOUSE, ROYAL GARDENS, KEW.

Influence of Stock on Scion. FROM the gardens at Newbattle, we have received through the kindness of Mr. MALCOLM DUNN, a bunch of Muscat of Alexandria Grapes, which has been grown by Mr. MACHATTIE on the Black Hamburg. The berries had the Muscat flavour, but were somewhat pear-shaped, pale olive-yellow, flushed with purple, especially near the base. Mr. DUNN tells us the foliage of the Muscat has much of the character of the Hamburg, especially near the stock, but is quite perceptible all the way along the rod (some 16 feet).

The diagram shows, on the left, the Black Hamburg stock (A), on a horizontal branch of which are grafted first a Muscat (1), and then a Duchess of Buccleugh (2); beyond which the Hamburg rod is directed upwards (AA), so that while it seems certain that the Muscat must derive some influence from the stock, it may possibly also derive some influence from the foliage of the Hamburg on the rod (AA). Not only the bunch sent to us, but the whole crop—nine to ten bunches—showed, we understand, the same peculiarity, and some were more highly coloured (rose or purplish) than the bunch we saw. The phenomenon was noticed at least two years ago, and Mr. MACHATTIE is of opinion that the Hamburg characteristics are gradually becoming more marked. No change has been observed in the Duchess of Buccleugh. The quality of all the Grapes produced by the Vine has been excellent.

Here, then, we have a clear case of the influence of the stock upon the scion, an influence the existence of which is so unaccountably denied by many gardeners, though if it does not exist, it becomes difficult to see why grafting should be practiced at all. Surely there is a change both in size and flavour when, for instance, certain Pears are worked on the quince?

We have recorded many such cases in our columns at various times. Some of them have been explained by the hypothesis that some sucker had grown up, or that accidentally some graft or bud was inserted of some other kind, and been overlooked. These are ingenious hypotheses certainly, but no attempt has been made to prove their correctness. The facts cannot be disputed, the explanations offered are at present hypothetical, so that for the present we lean to the facts, and to those inferences to be derived from them, which have the greatest amount of probability in their favour.

The fullest record of cases of this kind that we are aware of, is that of Dr. STURTEVANT, published in the "Transactions of the Massachusetts Horticultural Society in 1881," and reprinted in the *Gardeners' Magazine* for Dec. 10, 1881.

THE GHENT QUINQUENNIAL, 1893.—We learn that the Secretary of the Royal Agricultural and Botanical Society of Ghent, M. A. ROSSEEL, has resigned the office, and M. EDMOND CLAES that of Assistant-Secretary. M. ERNEST FIERENS, the Treasurer of the Society, one of the most notable amateurs of Chrysanthemums in Belgium, has been nominated as Secretary; and M. ARMAND DE MUELENAERE, one of the founders of the Orchidophile Club

of Ghent, as Assistant-Secretary. An exhibition hall, covering 2000 square metres will be erected in the garden for the quinquennial in April next, and by this addition the space devoted to purely horticultural exhibits will amount to 5000 metres.

ROYAL HORTICULTURAL SOCIETY.—Mr. BARON reported to the Fruit Committee, that during the operation of fruit drying, a temperature from 175° to 200° is required for Apples, and the time occupied is about three hours.

	When Dried.
10 lb. of fresh fruit of Cellini	give 1 lb. 8½ oz.
10 New Hawthornden 1 .. 11 ..
10 Blenheim Orange 1 .. 12 ..
10 Frogmore Prolific 1 .. 9 ..
10 Lord Suffield 1 .. 2 ..
10 Small's Admirable 1 .. 3 ..
10 Beauty of Hants 2 .. 4 ..

The parings and cores have to be added to the weight of the dried fruit when calculating the exact reduction by evaporation. For Plums the temperature required is about 250°, and the time taken is from eight to ten hours. The committee marked their approval of the success of the experiments by recommending a Silver-gilt Medal to Messrs. MAYFARTH & Co. for the apparatus, with the expression of their great satisfaction at the results achieved.

THE BRUSSELS ORCHIDÉENNE.—At the thirtieth meeting, on October 9, of the Brussels Orchidéenne, Botanical Certificates were awarded to *Isochilus graminifolius*, from M. Linden; and *Epidendrum* sp., from M. Garden. First-class Diplomas of Honour for *Odontoglossum Inseayi* var. *Imshootianum*, from M. A. van Imshoot (unanimously); and *Cypripedium* × *Warocqueanum*, from M. G. Warocqué (unanimously). First-class Certificates of Merit were adjudged for *Odontoglossum Inseayi leopardinum*, from M. A. van Imshoot; *Cattleya aurea*, from the same exhibitor; *Dendrobium formosum giganteum*, from M. F. Pauwels; *Cattleya chrysozona*, from M. Linden; and *C. Loddigesi violacea*, from M. A. van Imshoot. Second-class Certificates of Merit for *Miltonia candida grandiflora*, from M. A. van Imshoot; and *Cattleya Warocqueana*, from M. Linden; and First-class Certificates for Culture for *Cypripedium ceananthum superbum*, from M. G. Warocqué (unanimously and by acclamation); *Oncidium ornithorhynchum*, from M. Ch. van Wambeke; and for *Lælia Dayana*, from M. G. Warocqué.

PRESENTATION AT LOCKINGE HOUSE, WANTAGE.—Before giving up the charge of the gardens at Lockinge, Mr. J. ROSE, who had occupied the position for nine and a half years, was the recipient of some substantial marks of goodwill by his employers and others. Lord and Lady WANTAGE gave him a handsome silver bicuit-box, with a note expressive of their good wishes for his future welfare; from the under-gardeners came a marble clock; from the upper servants at Lockinge a dozen silver tea-spoons and a pair of sugar-tongs; and from the cricket club a handsome cruet-stand—this latter being presented by Lord WANTAGE, at a full meeting of the members and villagers. As has been mentioned in garden appointments, Mr. ROSE has now gone as head gardener at Wokefield Park, Reading.

A NEW PREVENTIVE FOR PLANT MILDEW.—Some years ago Mons. PELIGOT, in a communication to the Paris Academy of Science, pointed out that boric acid exercised an injurious action on Beans (vide *Comptes Rendus*, lxxxviii. p. 686), but the observation was forgotten, or, at least, was not recognised as capable of being applied to any practical purpose. In the course of some recent experiments on germination, Mons. J. MOREL reviewed the literature of the subject, and alighting upon this old observation proceeded to repeat the experiment. He then inquired into the action of various strengths of boric acid solutions upon Beans and Wheat. His conclusions are given in a memoir recently communicated to the Paris Academy of Science. He finds that boric acid has the effect of delaying or of completely preventing germination, according to the duration of its contact with the seed, and also to the strength of the solution employed. Wheat appears to resist the action of a boric acid wash

better than does the Bean. Borax, which is cheaper than boric acid, acts in a similar manner. It seems probable that these experiments may result in a practical application of great importance to horticulturists as well as to agriculturists, for when applied in very dilute solution, borax or boric acid does not injuriously affect the seed, but will completely arrest the development of various fungoid growths such as mildew. Experiments, we understand, are now in progress with the object of deciding what is the proper strength of solution to employ under varying conditions. Should Mons. MOREL's expectations be realised, then boric acid and borax may rank with, or even supersede, sulphate of copper (blue vitriol) as a preventive of mildew and similar growths.

FERMENTATION OF FARMYARD MANURE.—In a heap of ordinary farmyard manure complicated fermentations are in progress, and the rate at which they proceed depends upon the conditions of moisture and temperature which are present. The water furnishes the oxygen and hydrogen necessary for the formation of carbonic acid gas and ammonia, and the temperature determines the activity of the microscopic organisms which are really the cause of the fermentation. A recent paper by Herr T. SCHLESING, in the *Annales Agronomiques* (vide xviii., pp. 5 to 18), contains much information about the action of manure that is new, and some too that is merely confirmatory, though none the less valuable on that account, of the theories that are to be found in Aikman's little work on farmyard manure. In that part of a manure heap to which the air has access, as the temperature rises gradually owing to the aerobic fermentation, a purely chemical oxidation sets in, which goes on with increased rapidity after the heat has risen high enough to kill the microbes, and thus stop the fermentation which they are the cause of. It seems that there is a considerable production of ammonia during the fermentation which is not fixed in organic compounds, and is thus lost to the horticulturist who proposes to make use of the manure. Hence, care must be taken that the temperature does not rise too high, and this, perhaps, can be best governed by forking over the manure if it shows signs of getting too hot.

COLOURED LEAVES.—The great beauty at this season of many of the Maples, such as the Sugar Maple, the Norway Maple, the Red Maple, the Colchic Maple, Schwedler's Maple, and various others, always excites attention. We are reminded of them, moreover, by the receipt from Messrs. MAURICE YOUNG & SON, of Godalming, of sprays of various forms of the Norway Maple, *A. platanoides*, and especially of their form of the purple variety, the leaves of which, in spring, are of a deep purple colour, greening in summer, and turning to a brilliant crimson in the autumn, thus having an advantage over the nearly-allied Schwedler's Maple, which loses some of its beauty in autumn. Why planters do not avail themselves more of the various Maples we cannot imagine; they are beautiful at all seasons. It is not for want of telling—the Press is not backward in giving prominence to anything good, but it must be because people do not go and see for themselves, in the nurseries and parks.

A HORTICULTURAL SHOW AT VICTORIA.—We have a report before us of a flower show, held on August 25 of this year, in the Athenæum Hall, Collins St., Victoria. According to the reporter of the *Melbourne Argus*, the exhibition was an ill-arranged one, occupying the ground floor and a room on the first-floor; and the pathways were narrow, as were the benches in the lower floor, for showing off the plants, &c. The upper room afforded more space for promenading, and there was room for all the exhibits to be seen to advantage. It was a bulb and general exhibition, and Orchids were present in great numbers, and in some instances of large size and plentifully furnished with blossoms. A plant of *Cattleya Trianae* carried twenty-four blossoms; *Phalænopsis Schilleriana* was large and well-bloomed; *Schomburgkia undulata* had flower-stems, 6 feet

high; *Cypripediums*, *Dendrobiums*, *Angræcum* seaquipedale, *Saccolabium giganteum*, and other Orchids, in variety, were shown by different exhibitors. The usual species of tropical foliage plants that are cultivated in this country, find a place in the gardens of our countrymen in Australia; but it is less excusable that they should be found growing for the decoration of the greenhouse, the *Cineraria*, *Azalea*, *Calla æthiopica*, Chinese *Primulas*, and *Primula polyanthus*, and neglecting the numerous beautiful plants of their own country, scarcely one of which, if except *Dracænas* being mentioned in the report as having been shown. The fashion in gardening, at least in regard to the species of plants grown in pots, seems to be as faithful a reproduction as is possible of that which prevails so monotonously in the old country, even to the mode of decorating a dinner-table, filling an epergne, or making a spray for *SOPHONISBA'S* hair.

DUTCH HORTICULTURAL AND BOTANICAL SOCIETY.—At the meetings of the Society on September 14 and 28, the committee awarded the following: First-class Certificates to Messrs. E. H. Krelage & Son, of Haarlem, for *Gladiolus* hybr. *Lemoinei*, Leonard Kelway (introduced new plant); *Gladiolus* hybr. *Lemoinei*, Reverend W. Wilks (introduced new plant); *Gladiolus* hybr. *turicensis* (introduced new plant); *Kniphofia comosa* (insufficiently known plant); *Kniphofia hybrida* *Leda* (new plant); *Kniphofia hybrida* *Sirius* (new plant); *Montbretia crocosmiæflora*, Feu d'artifice (introduced new plant); to Mr. C. G. Van Tubergen Jr., of Haarlem, for *Colchicum Sibthorpii*, Baker (introduced new plant); *Nerine flexuosa*, Herb. var. *corulea* (introduced new plant); *Nerine elegans*, Hort. var. *corulea* (introduced new plant); *Nerine O'Brienii*, Hort. var. *lilacina* (introduced new plant); *Nerine sarniensis*, Herb. var. *corusca pallida* (introduced new plant); *Nerine sarniensis*, Herb. var. *Plantii* (introduced new plant); *Nerine sarniensis*, Herb. var. *insignis* (introduced new plant); to Mr. J. Walraad, Jr., of Boskoop, for *Abies Nordmanniana pendula* (new plant).

Second-class Certificates were awarded to Messrs. Groenewegen & Co. of Amsterdam, for *Nicotiana colossea*; to Messrs. E. H. Krelage & Son, of Haarlem, for *Dahlia* (Cactus), *Blushing Bride*; *Dahlia*, Mrs. Cock; *Dahlia* (Cactus), Garten director Siebert; *Kniphofia hybrida* *Solfatare*; *Kniphofia hybrida*, *Diana*; to Mr. H. D. Willinck Van Collen, of Breukelen, for *Echinacea purpurea* (insufficiently known plant); to Mr. L. Zuurendonk, of Haarlem, for a collection of *Coleus* hybr.; to Mr. C. G. Van Tubergen, Jr., of Haarlem, for *Canna*, *Jules Chrétien* (new plant); *Kniphofia* hybr. *John Waterer*; *Nerine amabilis*, Hort. var. *grandiflora* (introduced new plant); *Nerine humilis*, Herb. var. *splendens* (introduced new plant); *Nerine hybrida* *rosea* (introduced new plant); *Nerine sarniensis*, Herb. var. *corusca compacta* (insufficiently-known plant).

A Botanical Certificate was adjudged to Messrs. E. H. Krelage & Son, of Haarlem, for *Biarum Russelianum* Schott (introduced new plant).

Votes of Thanks were passed to Messrs. Groenewegen & Co., of Amsterdam, for *Helianthus latiflorus*; to Messrs. E. H. Krelage & Son, of Haarlem, for *Alstroemeria psittacina*, Frans Hals, Rembrandt, Van der Helso, Wouwerman, *Gladiolus* hybr. *Lemoinei*, Favorite, G. hybr. *nanceianus*, Kleber, G. hybr. *nanceianus*, President Carnot, *Helianthus latiflorus*, H. levis, H. strumosus, *Dahlia* (fl. simpl.), Duchess of Fife, and Mrs. W. C. Harvey; to Mr. C. W. R. Scholten, Jr., of Amsterdam, for *Crinum speciosum*, C. spec. *Venezuela*; to M. C. G. Van Tubergen, Jr., of Haarlem, for a collection of hulhous and tuberous plants, and nine species and varieties of *Nerioe*; to Mr. H. D. Willinck Van Collen, of Breukelen, for *Heliopsis levis*, *Polygonum compactum* and *Phytolacca acinosum*.

THE SURVEYORS' INSTITUTION.—The first ordinary general meeting of the session 1892-93 will be held on Monday, November 14, 1892, when the President, Mr. CHARLES J. SHOFFEE, will deliver

an opening address. The chair will be taken at 8 o'clock.

NATIONAL AMATEUR GARDENERS' ASSOCIATION.—A lecture on the construction and heating of greenhouses was given by Mr. CLARKE at the last meeting of the above Society, at the Memorial Hall, Farringdon Street, on Friday, October 14. A proposal to carry out one of the original objects of the National Amateur Gardeners' Association, namely, to hold a large exhibition of flowers, &c., in the City in 1894, is under consideration by the executive.

STOCK-TAKING: SEPTEMBER.—At first blush the figures presented by the Board of Trade Returns for the month of September are dispiriting. As to the imports side of the summary, the falling off is more in appearance than in reality: values have gone down (take Wheat, for instance) with a rush, as traders know, occasionally also the home consumer. For all that, trade in various industries is depressed, and capitalists are also suffering. In many cases lost ground is being recovered; and as hope springs eternal in the human breast, so we contrive to look forward for a better state of things at an early date, and to endeavour to achieve this. From the "Summary" of imports for the past month we take the following figures:—

IMPORTS.	1891.	1892.	Difference.
	£.	£.	£.
Total value for month	£34,989,301	£31,485,305	-2,603,996
§II.—(A.) Articles of food and drink—duty free	12,571,013	12,127,503	-443,510
(B.)—do., dutiable	2,967,724	2,520,935	-446,789
§VI.—Raw materials for textile manufactures (including Flax, Hemp, and Jute)	3,360,072	2,228,117	-1,131,955
§VII.—Raw materials for sundry industries and manufactures (including wood and timber, hewn, sawn, split, dressed; vegetable materials, for paper-making, &c.)	4,029,509	4,073,681	+44,172
§IX.—Miscellaneous articles (including Clover, Grass, Flax, Rape, Linseed) ...	1,196,565	1,007,458	-189,107
(B.)—Parcel Post ...	29,931	31,672	+1,741

From this it will be seen that the decrease in value is £2,603,996—the returns for the nine months show a gain in value of £696,337 as compared with the corresponding period last year. Incidentally, it may be noted, that we import from India some million tons of Wheat per annum, on the average of the past few years. Concerning the imports of fruit and vegetables, we make the following extracts:—

IMPORTS.	1891.	1892.	Difference.
Fruits, raw			
Apples bush.	197,478	405,825	+208,347
Cherries "	...	150	+150
Plums "	...	109,099	+109,099
Pears "	...	197,493	+197,493
Grapes "	...	195,135	+195,135
Unenumerated, ...	758,184	122,137	-636,047
Onions "	495,083	503,284	+8,201
Potatoes cwt.	49,825	87,555	+37,730
Vegetables, unenumerated, raw, ... value	£90,204	£91,211	+£1,007

The capacity of the British maw for this class of produce grows year by year—certainly a very gratifying matter of records. The "juniors" will not be overpleased to learn that a mildew has attacked and destroyed about a third of the Greek Currant crop—the "seniors" will reckon on the extra price for the remaining two-thirds!

EXPORTS FOR SEPTEMBER

show advance in value amounting to £1,688,684, as compared with September, 1891. Of course, the reader knows pretty well by this time that comparison with the past two years are, taken by themselves,

misleading—they were periods of inflation—rushing goods into the American and French ports in anticipation of an alteration in the Customs' duties. There is also to be noted that one of our customers—Japan—is fast becoming independent of exterior help in the production of many kinds of goods: in twelve months our exports to that region have fallen off nearly a million sterling. One export is worth special mention—that of silk to the Continent, for the purpose of being "thrown," the folks here being unable to do all of the work required. Considering the rapid strides now being made in this trade, manufacturers might endeavour to save this expense of export and import. Very satisfactory is it to note that the value of the exports to the United States last month reached £1,557,000, or an increase of nearly £300,000, on September, 1891; and a decrease of £519,000 compared with September, 1890. The working of the Melain (French) Tariff is just now receiving a practical illustration. The wine crop is short this year; in such circumstances it is usual to fall back on Spanish wines; the latest thing in tariffs places these out of reach; Currants would do instead—as noted above, the mildew has settled that against the French manufacturer or grower, so far as Greek Currants are concerned. It will be interesting to know how the crop will ultimately be made good. As the Indian Cotton crop for this year is reported to be a bad one, Lancashire may benefit by-and-by in the matter of exports of cotton goods, of which we may have to make a note in future "Stock-taking."

TECHNICAL INSTITUTE, DUNDEE.—The Dundee Horticultural Association, having for its aims the advancement of the science and practice of horticulture, will give a course of about twenty lessons and demonstrations, to commence in the Technical Institute on Monday, October 17, at 8 o'clock. The class will be conducted by Mr. D. STORRIE, who has been strongly recommended to the committee as a skilful and enthusiastic botanist and horticulturist. The introductory lecture will be free, and all gardeners or others interested are cordially invited. Mr. D. CROLL, president of the Horticultural Association, will occupy the chair. Professor GEDDES will give a course of one lecture weekly on botany during the summer term.

NATIONAL CHRYSANTHEMUM SOCIETY.—The conference on the suggested enlargement of Show-boards for Japanese Chrysanthemums, took place in the Library of the Royal Aquarium on October 12. Sir E. SAUNDERS, President, in the chair.

GARDENING LECTURES.—Mr. J. V. DUTTON has been appointed to give twenty-four lectures on the application of scientific knowledge to practice, at Waltham Cross.

KENT COUNTY CHRYSANTHEMUM SOCIETY.—We are informed by Mr. H. J. JONES, Hon. Sec., that at the fifth annual exhibition of this well-supported Society, to be held on Tuesday and Wednesday, November 1 and 2, at the Rink, Blackheath, more than £100 will be distributed in prize-money. The best prizes, those for the finest thirty-six blooms, will be £10, £7, £4, and £2.

CHISLEHURST GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.—The members of the above Association held their second annual meeting on Tuesday, October 4. The Secretary, having read his report and balance-sheet, which showed the Association to be in a flourishing condition, it being entirely supported by members' contributions, and after paying all expenses, a balance was left in hand. The Association has been recognised as filling a want long felt by the gardeners in the locality as a means for the better exchange of ideas on gardening subjects, that many an expression for its continuance was expressed. The election of officers, alteration of rules, &c., occupied the greater part of the evening. Afterwards promises of several papers were given, and the subjects promise to be of great interest. The Association meets every Tuesday evening, commencing the first Tuesday in October until the last in March.

THE ACTION OF THE ULTRA-VIOLET RAYS ON THE FORMATION OF FLOWERS.—This was the title of a paper read recently before the Physical and Natural History Society of Geneva, by M. CASSEPIER DE CANDOLLE, botanist, on September 1 last. The following is an abstract of the paper:—"Professor J. SACHS expressed his opinion in the year 1886 that the action of the ultra-violet rays was indispensable to the formation of flowers. The plants experimented with by Professor SACHS were *Nasturtiums* (*Tropaeolum majus*), since they can easily be cultivated in a dark place. His plan was to place several pots of the plants raised from seed, in large boxes, all the sides of which were impervious to light except one which alone admitted the light into the interior. To effect this, the side is fitted with a groove in which a colourless glass tube is inserted, on whose surface parallel lines have been ruled. The boxes are then placed in pairs side by side, and the tubes of one pair filled with pure water, while the other tubes contain a solution of sulphate of quinine which, though intercepting the ultra-violet rays, does not appreciably diminish the interior lighting of the box. The glass of the tube, which was very thick, would no doubt, of itself stop a portion of the ultra-violet rays, but we know that this absorption by the glass only affects extreme radiations exterior to the line N. of the spectrum. SACHS repeated these experiments during the summers of 1883, 1884, and 1886. The first time the boxes were placed on a window-sill facing the east, so that the plants received direct exposure to the sun during part of the morning. After sixty-two days (from June 15 till August 17), the two *Nasturtiums* which received the light through the tube containing water were found to be in full flower, while one of the plants cultivated behind the sulphate of quinine had produced no flower, and two others had only a few withered buds. In 1884 two boxes were placed in an easterly direction and two others in a southerly. This time the results were less accurate, as the sulphate of quinine turned mouldy. The plants behind the water flowered as before, but as the quinine turned a yellow colour, the plants behind it bore a certain number of flowers also. This proves that the plants will certainly flower if the light is conveyed to them through a liquid not nearly so transparent as water. On the next occasion SACHS managed to prevent mildew by adding a little sulphuric acid. The results were as follows: twenty plants receiving their light through the water produced fifty-six flowers in all, while the twenty-six plants behind the quinine produced only one flower of miserable appearance and a few buds. This time all the boxes were placed facing the north. SACHS was thus led to the conclusion that the ultra-violet rays produce in the leaves the substances necessary to the formation of the flowers. The experiments made by M. DE CANDOLLE began in 1889. The apparatus used was somewhat similar in design to that employed by SACHS, only much more elaborate in detail. Each pot contained two plants, and two pots were placed in each box. In order to prevent mildew, M. DE CANDOLLE renewed the quinine several times during the period of experiment (i.e., June 17 and August 29). His results were as follows:—The box with the pure water:

Number of leaves, 87 in one pot; in the other pot, 112.
Number of buds, 12 in one pot; in the other pot, 21.

On the other hand, the box with the quinine gave:

Number of leaves, 90 in one pot; in the other pot, 75.
Number of buds, 0 in one pot; in the other pot, 0.

The plants used this time were the "dwarf" *Nasturtium* instead of the "giant" used by SACHS. After these experiments M. DE CANDOLLE determined to try the action of the rays on the *Lobelia* (*L. erinus*). Many of these plants can be cultivated in the same box, and they have the advantage of flowering more quickly than the *Nasturtiums*. At the conclusion of the experiments M. DE CANDOLLE came to the conclusion that the loss of the ultra-violet rays lessened very considerably the flowering properties of the *Lobelia* without entirely suppressing them. These experiments could not be compared with those on the *Nasturtiums*, as this time *æsculi* was employed

instead of quinine. Now, even if the different experiments related above can be made to prove that the ultra-violet rays (included in the rays II and N of the solar spectrum), favour the flowering properties of certain kinds of plants, we are still in ignorance of the manner in which they act. Is it, as M. SACHS holds, by promoting in the leaves the formation of special substances of a reproductive quality, or are we to suppose that these rays can exercise a stimulative influence on the plants either by producing in the tissues some chemical reaction, or in a more direct way by augmenting the living force of the protoplasm, and causing influences which would transmit themselves step by step from the parts receiving the light to those which received none, such as the roots and the interior of the buds? It would be interesting to know if those of the ultra-violet rays which are absorbed by the glass, do or do not exercise an influence on vegetation. To carry out this research it would be necessary to light the plants in cultivation through quartz, an arrangement which would be difficult to effect in an apparatus of a large size.

INFLUENCE OF THE NATURE OF THE SOIL ON POTATOS.—Some careful experiments have during the past season been conducted by RAULIN in order to obtain some further data as to the influence of the nature of the soil on such vegetables as the Potato. He grew some samples of the Early Rose in the following kinds of soil:—

- A, a mixture of equal parts of B, C, D, and E.
- B, turf soil containing 64 per cent. of humus.
- C, soil containing 73 per cent. of limestone.
- D, earth containing 47 per cent. of clay.
- E, soil containing 75 per cent. of sand.

One-half (0.5 are) of each patch was treated with a quantity of a chemical manure containing—

Phosphoric acid	0.80 kilograms.
Nitrogen (as ammonium sulphate)	0.70 "
Potassium (as sulphate)	0.80 "
Plaster	1.00 "

The Potatos were planted in April, and gathered in September. The weights of the resulting tubers are given in the following table:—

With manure.	Without manure.
A, 203.49 kilogs. per are.	A, 148.00 kilogs. per are.
B, 145.10 " " "	B, 57.90 " " "
C, 125.90 " " "	C, 72.60 " " "
D, 73.10 " " "	D, 25.00 " " "
E, 43.50 " " "	E, 10.60 " " "

Twelve lots of nine tubers each were planted in soils of widely-ranging composition in order to discover the soil of maximum fertility. This seems to consist as follows:—

Clay, 2.64 per cent.	Sand, 67.20 per cent.
Humus, 23.39 " "	Limestone, 6.86 " "

So here we have, according to RAULIN, what may be termed an ideal soil for Potato growing. For further details, vide *Comptes Rendus*, xiv., pp. 1119—1122.

1 kilogramme equals about 2½ lb. avoirdupois.
1 are equals roughly an English acre.

COMPLIMENTARY DINNER AND PRESENTATION.—On the 13th inst. a few personal friends of Mr. W. MARSHALL among the judges and exhibitors at the recent shows at Earl's Court, invited him to dinner in the Exhibition Building, by way of showing their appreciation of his exertions in assisting to make the various shows held there successful. Mr. Harry Turner, who presided, was supported by Messrs. J. Wills, J. Laing, H. Williams, P. Barr, H. Herbst, W. Poupert, J. Walker, A. Turner, B. Wynne, R. Dean, and others. In the course of the evening the Chairman presented Mr. Marshall, on behalf of certain friends with a charming Orchid picture, from the Art Gallery, painted by Miss Macfarlane, the subject being an antique Spanish vase, containing blooms of *Brassavola Digbyana*, and *Cypripedium barbatum*, with a flower of *Rose Gloire de Dijon* at the base. Mr. Marshall, who was evidently much gratified by the gift of the picture, suitably responded, alluded to the success of the various shows, and of the International Exhibition itself, and expressed his belief that the gardening charitable societies would be remembered when the accounts were made up.

PUBLICATIONS RECEIVED.—*Das Kleine Haus mit Garten.* LOTHAR ABEL, Vienna, Pesth and Leipsig. (A. HARTLEBENS, Verlag.)—*The Iron-mongers' Chronicle.* No 1, Vol. I. Published at 139 and 140, Fleet Street, E.C.

HOME CORRESPONDENCE.

PLANTING APPLE TREES IN HEAVY SOIL.—The time for commencing to plant fruit trees will soon arrive. Sometimes, from lack of experience and what it teaches, mistakes are made in planting the trees in heavy soils, in such a way that in six months afterwards the roots are too deep to admit of the best results. Instead of filling in the deeply-dug holes quite up to the level of the natural soil, or 6 inches above it, before putting the tree in position, they are planted so that they may look well at the beginning. I have a good example of the desirability of keeping certain kinds of Apples higher than the natural level in the garden at this place. Two years since, a bush of the Schoolmaster Apple was planted with others in the kitchen garden in such a manner that at the present time the bush is just on a level with others in the garden, and, as one would think, the roots at the right depth. The fruit on this bush is much cracked and otherwise disfigured, presumably by reason of the roots being too deep, and consequently in an ungenial medium. In another part of the garden a tree of the same variety affords a striking contrast to this one. This tree was removed to its present site last October, and was raised fully 1 foot above the adjacent level, a good-sized mound, in fact, being raised about the tree, made-up mainly of the staple—a retentive heavy loam—to which were added decayed vegetable refuse and wood ashes. The roots were mulched during the summer with stable-manure in a partly rotted state. The fruit borne by this tree affords a great contrast to that from the bush, not a speck or crack being visible, but perfect in every way. Some varieties of Apples are able to withstand the evils of deep planting, while others can barely exist at all; it being difficult to ascertain which these are, without testing them, it is the safer plan to plant them on raised mounds where the soil is heavy. E. M.

TUBEROUS BEGONIAS UNDER TREES.—A bright spot, created by a quantity of tuberous Begonias, in good bloom, and quite unharmed by frost, was observed a few days since at Mr. B. R. Davis' Nursery, Yeovil, whilst everywhere in the open the plants had been cut down by the frost of September 18, which was severer in Somersetshire than around London. Here, beneath a broad-headed purple-leaved Beech, the Begonias were fresh and beautiful. This fact would admit of two useful lessons—first, that Begonias can be made to do well beneath trees if the soil be well made, and the lower branches are some 15 feet from the ground; second, that in thus planting Begonias, it is possible to have them blooming freely fully one month later out-of-doors than in the unsheltered open ground. It was something of a surprise to one well accustomed to see the wealth of Begonias found in some London nurseries or near the metropolis, and believed that these alone were the cream of the strain, to find such a splendid strain, or rather strains, so far from London. I was taking a quiet walk round Yeovil streets when I came across this Begonia nursery. There can be no question whatever as to the merits of the Yeovil strains, and, as elsewhere, they are being continually cross-fertilised for the production of variations. The flowers shown recently at the Drill Hall evidence the progress being made in evolution in Begonias. A. D.

NARCISSUS BROUSSONETII is very beautiful, and apparently a very free flowerer. I have it now in bloom, four scapes, each with a head of six or eight large pure white flowers. This is the second time the bulbs have flowered since I had them, and the bloom is more ample, and in every way better this second time than it was the first. M. F.

ROSA RUGOSA.—In your paper of October 8, Mr. Smith, of Daisy Hills, Newry, says there are two kinds of *Rosa rugosa*, one with large foliage and fruit, the size of a large Plum; the other no bigger than a Red Currant, the foliage correspondingly smaller. The typical form has fruits of the shape of the earth, but flattened at the poles. R. r. pyriformis has small leaves and pear-shaped fruit, thorns of both

sharp. I beg to say that I have two trees of *Rosa rugosa*, one has pink flowers, and the other white; the leaves of both are the same size, and until this year the white flower also had a bright yellow fruit as large as the pink one, but this year the fruit of *Rosa r. pyriformis* is also dark red. The trees are on the same border, and the soil is the same; they are sheltered from the north by a south wall. I send you some leaves and fruits, and shall be obliged for any information to make No. 2 bear yellow fruit. No. 1 has thrown out two fine suckers, which have borne flowers and fruit this season. *M. T.* [We do not know how to advise you. Ed.]

THE EARLY RIVERS NECTARINE.—I hope gardeners will show how they appreciate Mr. T. F. Rivers' kind offer "by subscription" of the above grand new Nectarine. To gardeners who have not seen the fruit but know Lord Napier Nectarine, I may say, Early Rivers is even better in size, a good colour, free bearer, fine flavour, and three weeks earlier than Lord Napier. Just imagine us sending to London in first week in May such fine fruit, or in April, if asked for. *Jas. Hamilton, Byrkley Gardens, Burton-on-Trent.*

PELARGONIUM PRIDE OF TRENT.—Last season, I believe, Mr. Geddes of Thrumpton Hall Gardens had a letter in the *Gardeners' Chronicle* calling attention to the great effectiveness of a scarlet-crimson bedding Pelargonium, raised by Mr. Anderson of Clifton Hall Gardens, called by him Pride of Trent, and which was being used with much satisfaction in the flower garden at Clifton Hall. Not having personally seen it bedded out, I paid a visit to Clifton about a week ago, and, though the weather was very unfavourable—indeed, the usual weather we have had lately, wind and rain in pretty considerable force and quantity—what I saw there enables me to endorse and emphasise all that Mr. Geddes said last year. It is a scarlet crimson; the crimson in it being something like that of Henri Jacoby, but the scarlet colour in Pride of Trent adds to it a superiority in attractiveness over Messrs. Pearson's excellent variety, and causes it to be conspicuous wherever the eye lights upon it. It attracts at once, and satisfies. One of its chief merits—a very great one, as all flower-gardeners know—is its weather-resisting properties; for, though there had been drenching rains before, and during my visit, which had robbed the flower garden of much of its summer glory, specially as to Pelargoniums, the beds of Pride of Trent had a brightness about them which made them noticeable even to the ordinary observer. Pride of Trent is certainly a scarlet-crimson Pelargonium we ought to hear more of, and all his neighbours hope that Mr. Anderson may see his way towards putting it into commerce. *D. J. Graham, Forest House Gardens, Nottingham.*

THE WINTER MOTH AND THE WILLEDEN PREPARED PAPER.—The Willesden Paper and Canvas Company inform me that they have many applications for their canvas and prepared brown paper for use on fruit trees against the winter moth, and ask for particulars as to mode of use. We use their "Brown Canvas DD extra," cut into strips, 4 inches wide, and prepared brown paper of the same width; the paper is put round the stem of the trees about 1 foot from the ground, and kept in its place by tarred twine; the canvas is then placed over it and secured in the same way; common cart-grease, without tar, is then spread over, this catches many females (wingless) of the winter moth and some other moths; more cart-grease should be added from time to time when it dries. Our Apple, Quince, and Damson trees were much injured till we adopted the above remedy, and have been all right since. The bands should be on before the end of October. *George F. Wilson.*

THE LATE MR. BULLEN, GLASGOW BOTANIC GARDEN.—There is a peculiar sadness in the sudden removal of our late friend Mr. Bullen, a man so estimable, who enjoyed the respect of a wide circle of friends, and whose career was a marked success. By his great tact and indomitable perseverance, Mr. Bullen piloted the Glasgow Botanic Garden through untold difficulties, and seemed to have attained the zenith of his triumph when the end came so suddenly. There is not a horticulturist in the North whose popularity surpassed that of the late Mr. Bullen. His urbanity, courtesy, and kindheartedness to everyone with whom he came in contact was proverbial in and around Glasgow. I was conducted last summer by Mr. Bullen with some friends, through the spacious glass structures of the Botanic Garden, and was struck with the health, clean-

liness, and good culture shown by all the plants under his charge. When I last saw him it was at the Autumnal Horticultural Exhibition held in Glasgow, where he seemed to have an exalted position among his fellows, and his kindly greeting to all and sundry, attached to him many friends. He never hid his stores of horticultural knowledge, but was always communicative to all enquirers. The world is rendered poorer by the loss of such a man; and we all deeply regret that we shall see his genial face no more. *M. Temple.*

GALEANDRA NIVALIS.—*Apropos* of this species, I may remark that we have had it in bloom for the last six weeks, and that it flowers every year. *J. Tabor, Ashford, Kent, October 12.*

PEACH TREES AND DRY BORDERS.—I write to thank you for answering my question on Peaches, and to say I found the cause was that the trees were planted more than 2 feet deep, and were in bad sub-soil, and although I had afforded the soil many gallons of water, it had never penetrated to the roots. These were cankered and many dead, and the soil looked as if it had had no water since the trees were planted, which must have been a good many years ago. I have written this thinking perhaps it might afford a hint useful to others who may be wondering why the huds fall, and the trees do badly. *George Hasell, Vale Mascal, Hollington Park, Hastings.*

CHANGES IN YORKSHIRE GARDENS.—It may be of interest to note that changes occurring in Yorkshire gardens show the somewhat long services of the three gardeners now leaving—I allude to Harewood House, Leeds, where Mr. James Fowler has been thirty-six years; Studley Royal, Ripon, where Mr. John Clarke has been about thirty-four years; and Newby Hall, Ripon, where Mr. Wilkinson has lived about thirty-five years. The three estates are not very far distant from each other. Mr. Fowler has entered into business as a seedsman and florist with his son, who has been trained to the business, as manager. Mr. Clarke and Mr. Wilkinson retire from active service, and all of them are well known and respected in gardening circles hereabouts. Mr. Clarke, in particular, has been long known as an excellent gardener, and an estimable man in all the relations of life. As one proof of his capacity and honesty of purpose, I may mention that for some twenty-eight years he has been selected as a judge at one of the largest local horticultural exhibitions. I feel sure he will carry into his well-earned partial retirement from active service the respect and good wishes of all his numerous Yorkshire friends and acquaintances, and who reside in many parts of the country. It may be necessary to add, that successors to each have been appointed. *Yorkshire Gardener.*

CROCOSMA.—Was this or *Crocasmia* the name given to the plant formerly called *Tritonia aurea* when made into a separate species? *Genera Plantarum* has "*Crocasma*," referring for authority of the name to Planchon's *Flore des Serres*; but Nicholson's *Dictionary*, and nearly all catalogues have "*Crocasmia*." No doubt the word is meant to signify "smelling of Saffron," and we might expect it to follow the analogy of "*Coprosma*," "*Diosma*," and one or two similar names coined by botanists, which were made by them of the feminine gender. The only classical model of such a plant-name is *Onosma*, which is of the neuter gender, as all words ending in "ma" are in Greek. This word has probably nothing to do with smell, its origin, and the plant to which Dioscorides applies it, being altogether uncertain. *C. Wolley Dod, Edge Hall, Malpas.* [We have not Planchon's original description at hand, but, we believe, he spelt the name erroneously as *Crocasmia*. Ed.]

LARGE TREES.—Your correspondent, Chas. C. Hurst, in this week's *Gardeners' Chronicle*, asks for measurements of large trees. I may say, there is in the garden here a Plane measuring 19 feet round the stem, 6 feet from the ground (which is the smallest part of stem), and from the stem to the end of the branches on either side, 50 feet, and it is about 100 feet high. *H. T. Brasier, Palace Gardens, Ely.*

IRIS NEPALENSIS.—Mr. Baker has kindly called my attention to a form of *I. nepalensis*, described recently by Collett and Hemsley (*Journ. Linn. Soc.*, xxviii., No. 189—191, p. 136), as found in Shan Hills, of which I regret to say I was ignorant. Mr. Baker suggests that this is identical with the var. *Letha*, which I described in last week's *Gardeners' Chronicle*.

It is possible this is so. But the authors in question describe their plants as a depauperated form, 3 to 4 inches high. My plant so far from being a depauperated form, is much more vigorous than the type, and the leaves are a foot or even more long, though the flower is sessile. Moreover, the full-grown leaves show none of the purple lines and dots spoken of by Collett and Hemsley, and I do not remember noticing them in the very young leaves. My plant is so distinct from the type in general aspect, that many would not hesitate to consider it a new species; it ought at least to have a varietal name, and since Collett and Hemsley did not think their specimen worthy even of this, I suppose the name I have suggested holds good. *M. Foster.*

FINE POTATOS.—It might interest some of the readers of your valuable paper to know that when digging up our Magnum Bonum last week, we came across two fine specimens, one tuber weighed 2 lb. 10 oz., the other 1 lb. 14 oz. The whole of the Potatos were very fine. *A. Bagg, Bishop's Hall, Romford, Essex.*

SOCIETIES.

ROYAL HORTICULTURAL Scientific Committee.

OCTOBER 4.—Present: Dr. M. T. Masters in the chair; Mr. Morris, Mr. McLachlan, Mr. Blandford, Dr. Müller, Rev. W. Wilks, Dr. Scott, Dr. Bonavia, Professor Church, and Rev. G. Henslow, Hon. Sec.

Bouillie bordelaise.—With reference to this preparation, Mr. Morris stated that it had been thought advisable by some persons to water the soil with it, and M. Cornu, as recorded in his letter read at the last meeting, appeared to favour this view. It was, however, the general opinion of the members present that this procedure would undoubtedly sterilise the soil, and so prove highly injurious by arresting nitrification. Some further discussion arose with reference to the best manner of knowing when the bouillie was in a proper state for application, as several failures in its use had resulted from the copper-salt being still present in the solution. Dr. Russell, as recorded at the last meeting, appeared to rely upon the absence of a blue colour when 2 or 3 inches in depth of the clear fluid was looked through; another suggestion, made by Dr. Müller, being the application of a small quantity of liquid ammonia. If there be any copper present, the bouillie would become blue. Professor Church remarked that although all the sulphate of copper might be changed into the hydrated oxide, yet if any small quantity of the latter be left suspended in the liquid, and not entirely precipitated, the blue colour would still appear on the addition of ammonia. The simplest and most efficacious test would be to place a piece of clean iron (e.g., a knife blade free from grease) into the solution for about 5 minutes; then, if no film of copper were deposited on the iron it might be concluded that the mixture was in a proper condition for use. It was further added by Dr. Müller, that great care is required in using the lime, as, if it were not most thoroughly pulverised in water, portions would not come into action at all. The lime, too, must be of the best quality, and not from a quantity which had been kept for any time exposed to the air.

Prevention of Smoke and Fogs.—Mr. Michael forwarded the following report upon Col. Dulier's process for the prevention of smoke and fogs:—

"As requested by the committee, I have inspected Colonel Dulier's apparatus at 51, Sloane Gardens. The process is especially applicable to domestic fires, including those of the ordinary English type. Shortly stated the process is as follows—viz., steam (not under pressure) is generated in a small special boiler behind the kitchen range, and is allowed to mix with the smoke in the flue; it may be introduced either at the top or the bottom of the flue. The mixed smoke and steam does not pass through a chimney-pot into the open air in the usual way, but is conducted into a condenser on the roof of the house, which receives all the flues of the house. In this condenser the steam is condensed, and falls into very fine rain, thus washing the smoke and carrying down carbon, sulphurous acid, &c., the whole being carried off by a drain. It is claimed that the condensed steam carries down practically the whole of the free carbon, and also a third to a half of the sulphurous acid when the air temperature in the open is 50° Fahr. or above, and more than a half when the temperature is lower. It does not appear that any experiments have yet been made to

ascertain what proportions of the other residual products of coal combustion are carried down. The process appears to me to be simple, automatic, and well worthy of further investigation and encouragement. A wet rag placed over the discharge aperture of the condenser, where the hot air and gases escape, is not blackened and does not collect soot, and the face may be held over the same aperture without any particular inconvenience being experienced. It is further claimed that the apparatus prevents the possibility of a down draught in the chimney, and also effects a considerable saving in fuel. The present apparatus at 51, Sloane Gardens, has been erected for the purpose of experiment and demonstration only, and would, I fear, be much too costly to be enforced for general use in small houses; but it is the first made, and could probably be greatly simplified and reduced in cost. Colonel Dulier would be happy to exhibit the apparatus to the Fog Sub-committee on their applying to him at 27, Sloane Gardens. The apparatus used by the chemists who tested the absorption of sulphurous acid, &c., is still in No. 51, Sloane Gardens, and Colonel Dulier would place it at the service of any chemist connected with this Society who might be inclined to make further investigations."

The thanks of the committee were given to Mr. Michael for his report.

White Ants from La Rochelle.—Mr. McLachlan exhibited specimens of the *Termites lucifugus* received from La Rochelle, the injuries caused by them having been described at a previous meeting. They are small, being about half an inch long, and in the larval condition.

Artichoke Gall.—He also exhibited a specimen of a gall, probably produced by some species of cynips.

Cladosporium on Wheat.—Mr. Plowright sent specimens showing this disease, with the following communication:—"During the last season this disease has been exceedingly common in the Wheat in various parts of England. No district has probably suffered more from it than the eastern counties. It is often present with us, but I have never seen it so abundant as this year. Whole fields were blackened by it, and many persons mistook it for Wheat mildew, with which, of course, it has no affinity. Until recently the *Cladosporium* was regarded as a saprophyte, but recent investigations show me that it can also exist as a true parasite. During the harvest the difference between Wheat mildew and the *Cladosporium* disease is very apparent, for where the last-named is present to any extent, the reaping-machine is surrounded by a cloud of dust. There is nothing to prevent both fungi occurring in a Wheat crop simultaneously, but, of course, the mildew is not dusty. Prof. Eriksson, of Stockholm, a few years ago, called attention to the prevalence of *Cladosporium* on Rye in Norway and Sweden, and pointed out that it all occurred on the grain; and further, that when the diseased Rye was consumed, it gave rise to a series of symptoms, among which were diarrhoea, vomiting, and especially derangement of nerve centres, producing dizziness and a staggering gait, like that of a drunken man. The grain of Rye, being less covered by the chaff, is more liable to have the fungus upon it than is the case with the Wheat. Professor Woronin last year was called upon by the Russian Government to investigate a series of cases in which the above-named symptoms were produced by its consumption. He came to the conclusion, however, that the poisonous properties were induced rather by *Fusarium roseum* than by the *Cladosporium*, although the latter was very abundant on the affected grains. As will be seen from the specimens sent, the *Cladosporium* is especially abundant on the chaff. Such a development of parasitic life cannot but be detrimental to the Wheat affected by it, and it is probable that the *Cladosporium* has much to do with the poor yield so many agriculturists complain of this year. This is a subject into which the Agricultural Department should inquire at once."

Cronartium ribicola.—Mr. Plowright also sent specimens of *Pinus Strobus* attacked by the acidiform stage of this fungus, with the following communication:—"At a recent meeting of the Scientific Committee specimens of this fungus on Currant leaves were exhibited, gathered in the garden of Mr. C. G. Boyes, Oakwood House, Setch, near King's Lynn. On August 13, I again visited the garden and examined the Pines, in order to find, if possible, the branches affected by the *Peridermium*. This I was successful in doing, and herewith send one of the affected branches. It will be seen that the mycelium of the *Peridermium* has caused hypertrophy of

the affected branch. The peripheral extremity bears a sickly tuft of foliage, but the branch itself is evidently dying, although at its base it shows the enlargement due to the mycelium extending downwards. There are two trees affected about 15 yards from the Currant bushes. I have also observed the *Cronartium* on Currants in the garden at Middleton Rectory." A vote of thanks was given to Mr. Plowright for his interesting communications.

Green-fruited Elder.—Mr. Henslow exhibited sprays of this rare form of the common Elder from a tree in his garden at Ealing. The foliage differs from the common form in being darker in colour, the two halves of a leaflet approximating each other as in the Portugal Laurel, the marginal teeth being curved forwards, whereas in the common form the leaf is paler green, the leaflets are flat, and the teeth straighter. The berries of the green variety are globular with ten veins, resembling Currants, the ordinary form being oblong and black. The taste is the same in both.

Floral Committee.

OCTOBER 18.—On this occasion a very excellent show of hardy fruit was brought together at the Drill Hall, James Street, Westminster, which was temptingly displayed on long tables in the centre of the hall. A pretty lot of Orchids, some rare and all beautiful, graced a table on one side; and a fine stand of several hundred Ferns, in fine condition for the time of year, well-furnished the opposite side of the building. Cycads, Chrysanthemums, tuberous Begonias, and coloured foliage formed the more prominent part of the remainder.

Present: W. Marshall, Esq., in the chair, and R. Dean, B. Wynne, H. Herbst, C. T. Druery, E. T. Bause, R. Owen, G. Phippen, R. E. Lowe, T. W. Girdlestone, W. C. Leach, W. Furze, H. H. D'Ombra, G. Gordon, C. Jeffries, H. Cannell, J. Walker, T. Baines, J. Fraser, C. Noble, W. Bennett Po, G. Paul, H. Turner, Owen Thomas, N. Davis, and E. Mawley.

Mr. H. B. May, Upper Elmton, staged a large and tastefully arranged group of foliage plants, Ferns, &c., including some nice Crotons, and very ornamental varieties of Ferns (Silver-gilt Flora Medal). Messrs. Cannell & Sons, brought some single-flowered tuberous Begonias, that had been lifted from the open ground about a fortnight since. These were surprisingly good after the severe weather we have had. Also some zonal Pelargoniums, Madame Boudeville, a pale salmon-pink with rose margin (single) received an Award of Merit, as did also Raspail Improved, a semi-double rosy-crimson variety. There were included in the collection a few plants of "Double New Life." It is striped like the single one, and is a mixture of scarlet and white. The plant is a descendant of the well-known Vesuvius, which threw the single-flowered variety "New Life," and a zonal with double deep scarlet blossoms, named "Wonderful," which latter in its turn produced this double-flowered New Life—a curiosity of white and scarlet flowers, arranged in a many-flowered truss. Some sprays of *Physalis Alkekengi* completed the exhibit (Bronze Banksian Medal).

From the Royal Garden, Windsor, came a beautiful group of plants of *Caruina Marguerita*, in colours from palest pink to dark purple. They were from seed sown on February 18, 1892 (Vote of Thanks).

Two very finely-flowered pots of *Nerine crispa* came from Mr. T. Bones, Tower House, Chiswick. They were in 6-inch pots, and had about two dozen spikes to each pot.

The Duke of Northumberland, Albury Park, Guildford (gr., Mr. C. Leach) sent a fine collection of sprays of ornamental autumn foliage, including *Euonymus europaeus*, *Audromeda arborea*, *Cornus sanguinea*, *Azalea pontica*, *Rhus cotinus*, *Liquidambar styraciflora*, varieties of *Acer*, *Viburnum*, &c. (Silver Banksian Medal).

A few sprays of that most delicate and beautiful of all the *Ixoras* (*Ixora Westii*), were sent by Mr. Jas. Hudson, gr. to Lord Rothschild, Gunnersbury House, Acton.

To show the difference between Aster "Jao. Wood" and A. "Harpur Crewe," the Rev. W. Wilks sent blooms of each; also a bloom of the old form of *Colchicum speciosum*.

Mr. Arthur Knowles, nurseryman, Horsel, Woking, sent a box of *Daphne Cneorum*. A group of clean healthy *Cycas revoluta* came from the nursery of Messrs. E. D. Shuttleworth & Co.; the plants were young, and illustrated the decorative value of the order in a marked degree (Silver-gilt Medal). Some sprays of *Berberis Thunbergii* and *Quercus ameri-*

canus splendens, both deeply coloured, came from Mr. Anthony Waterer, Knap Hill, Woking, Surrey.

The authorities of the Royal Gardens, Kew, contributed a white variety of *Thunbergia grandiflora* (T. g. var. *alba*); also a seedling *Streptocarpus*, the result of a cross between the new species, *S. Galpini*, and *S. rex*. Both the species and the hybrid are very beautiful, but the seedling has larger blooms, and the white throat of the species has given place to a dark purple one in the hybrid. From the same garden came *Satyrion sphaerocarpum*.

The advance guard of the "mums" put in appearance on this occasion, represented by a few new varieties of great promise. Foremost was William Seward, sent by a gentleman of this name residing at Hanwell, who last season exhibited at one of the meetings of the National Chrysanthemum Society a number of yearling seedlings of a character that promised remarkably well, and one of them is the variety just named. It is a large reflexed Japanese, of a rich crimson-maroon colour, with a bronzy-buff reverse, having great breadth of petal; and it is a singularly fine exhibition variety (Award of Merit).

Mr. W. J. Godfrey, nurseryman, Exmouth, had *Beauty of Exmouth*, a large reflexed white Japanese, pure in colour, deep and full, and a decided acquisition to the October-flowering varieties (Award of Merit). *Duchess of Devonshire*, Japanese, pale pink, with silvery reverse; was not in good condition.

From Mr. R. Owen, nurseryman, Maidenhead, came Mrs. Myers, a large reflexed pure white Japanese, having a yellow centre, great depth of substance and breadth of petal (Award of Merit); *Baron Hirsch*, a very fine and distinct incurved variety, pale orange Cinnamon or bronze reverse; *amaranth surface*, large, full, and of fine shape (Award of Merit); Mr. Owen also had *Edith Owen*, an incurved Japanese, pale pink with silvery reverse. From Mr. H. J. Jones, nurseryman, Lewisham, came Mrs. A. G. Hubback, an incurved Japanese of a bright rosy-purple tint with silvery reverse, two blooms only being shown; *Madame E. A. Reg*, also an incurved Japanese, pale ground, the points of the petals bright purple, very pretty and pleasing; also *President Carnot*, a new French incurved variety, buff reverse, tinted with yellow, and bright crimson surface, which will probably be seen again. Mr. W. Wells, nurseryman, Earlswood, had Mrs. W. R. Wells, a white sport from *Vivian Morel*, but there is a tendency on the part of this variety to sport to pale forms; *William Wells*, and deep primrose sport from *Mlle. B. Pigmy*; *Miss Gorton*, a pretty blush Japanese; *Margot*, a charming hue of rosy-pink; Mr. R. Bahaut, La Chirine, a good yellow, in the way of *Sundowner*, and others. From Dr. Franklin, Reigate Hill (Mr. C. Rutchings, gr.), came a stand of thirty-six blooms of Japanese. Conspicuous among them were *Edwin Molyneux*, *Avalanche*, *Sunflower*, *Stanstead Surprise*, Mrs. W. H. Lincoln—a very fine incurved yellow, *Mons. Freeman*, *Elaine*, &c.

Orchid Committee.

Present: Dr. Maxwell T. Masters, in the chair; and Messrs. Jas. O'Brien, Sec.; Jas. Douglas, E. Hill, J. Jaques, Rev. E. Handley, De B. Crawshaw, H. Williams, and H. M. Pollett.

An extensive group of Orchids was arranged by Messrs. B. S. Williams & Son, Victoria and Paradise Nurseries, Upper Holloway, N., among them being fine examples of over twenty varieties of *Cypripedium*, including the fine *C. Pritchardianum* × *Williams' var.*, *C. vexillarium superbum* × *C. selligerum rubrum* × *C. insigne Mooreanum*, *C. Morganiae*, and *C. cananthum superbum*. Also among Messrs. Williams' exhibits were *Bollea Patini*, *Dendrobium Phalaenopsis Schroederianum*, *D. Goldiei*, *D. Dearei*, *D. superbiens*, *Oncidium Kramerianum*, *O. Papilio*, *O. P. Eckhardti*, *O. Ornithorhynchum*, some fine *Odontoglossums*, *Pleiones*, *Epidendrum Cooperianum*, &c. (Silver Banksian Medal).

Philip Crowley, Esq., Waddon House, Croydon (gr., Mr. W. King), staged a group of Orchids made up of fifteen finely-flowered plants of *Odontoglossum grande*, four good forms of *Vanda Kimballiana*, *V. tricolor*, well-bloomed; and a nice variety of the old *Cymbidium giganteum* (Bronze Medal).

Messrs. F. Sander & Co. sent some rare Orchids, one of the most beautiful being a specimen of the elegant *Platyclinis Cobbiana*, with many of its pendent spikes of white flowers with yellow centre. Another rare species was *Cattleya Brymeriana*, and among other good things were *Cattleya aurea chryso-toxa*, which has given such a remarkable series of beautiful variations; *Masdevallia gorgona*, *M. Roezlii*, *Cœlogyne fuscenscens*, and *Brassia maculata*.

George Hardy, Esq., Pickering Lodge, Timperley, Cheshire (gr., Mr. W. Holmes), sent a four-flowered spike of the true *Cattleya Massaiana*, which may be likened to a form of *C. Hardyana*, with sepals and petals mottled rose and white; also *C. anrea*, and a spike of *Cypripedium* × (*caudatum* × *Ainsworthii*), under the name *C. Hardyannum* ×. It bore a great resemblance to *C. macrochilum* ×, illustrated in the *Gardeners' Chronicle*, September 19, 1891, p. 343, and the committee desired to see it again.

Thos. Statter, Esq., Stand Hall, Whitefield, Manchester, showed a 3-flowered spike of a good bright form of *Cattleya aurea*.

Messrs. Linden, L'Horticulture Internationale, Parc Leopold, Brussels, sent a yellow *Odontoglossum*, under the name of *O. Inslayi Lindenii*, but the flowers were too much damaged to admit of the merits of the plant being accurately judged.

Fruit Committee.

Present: P. Crowley, Esq., in the chair; and Messrs. J. Lee, T. F. Rivers, G. Taber, T. J. Saltmarsh, J. Wright, A. Dean, A. H. Pearson, G. H. Sage, G. Wythes, J. Hudson, H. Balderson, J. Willard, R. Hogg, Harrison Weir, and J. Cheal.

We have seldom seen a better collection of fruits at the Drill Hall than was there on Tuesday last. In addition to the Apples, Pears, and Grapes, for which prizes had been offered, there were many and large exhibits of every variety of fruit in season. The 1st class was for ten dishes of Apples grown in the open (six dishes of cooking and four of dessert) amateurs, and the 1st prize was secured by Mr. A. W. Porteous (gr. to E. H. Watts, Esq., Devonhurst, Chiswick), whose collection comprised Lord Derby, Warner's King, Prince Bismarck, Emperor Alexander, The Queen, Peasgood's Nonsuch, Cox's Orange Pippin, Gravenstein, Worcester Pearmain, and Ribston Pippin; Mr. Nicholson, gr. to J. W. Melles, Esq., Sewardstone Lodge, Chingford, was 2d.

Pears were solicited subject to the conditions that they had been grown in the open, that they were dessert varieties, and of six fruits to the dish, and six dishes (amateurs). J. W. Melles, Esq., was 1st, with commendable specimens of Pitmaston Duchess, Marie Benoist, Doyenné du Comice, Louise Bonne of Jersey, Rivers' Princess, and Beurré Diel; the Duke of Northumberland, who included fine specimens of Pitmaston Duchess, was 2d.

For six bunches of Grapes, not less than three varieties, the 1st prize was awarded to Messrs. Rothschild, Gunnersbury House, Acton (gr., Mr. Jas. Hudson), who showed finely-coloured and well-finished bunches of Muscat of Alexandria, Black Alicante, and Lady Downes' Seedling; the 2nd position was filled by Mr. Thos. Oaman, The Gardens, Ottershaw Park, Chertsey. This last exhibitor also received a 1st prize for six bunches of Grapes, of not less than three varieties (for flavour). The varieties were Muscat of Alexandria, Mrs. Pearson (good), and Mrs. Pince's Muscat; this latter variety was not well finished.

Mr. Geo. Wythes, gr. to the Duke of Northumberland, Syon House, exhibited a large and good collection of Apples and Pears, the most notable being—Apples, Cox's Orange Pippin, Alfriston, Blenheim Orange, Red Astrachan, Cellini Pippin, Worcester Pearmain, Warner's King, and Peasgood's Nonsuch. Pears, Pitmaston Duchess, Duchess d'Angoulême, and Beurré Diel (Silver Knightian Medal).

Mr. Samuel Mortimer, The Nurseries, Rowledge, Farnham, brought some good bunches of Black Hamburg and Alicante Grapes; these were well-furnished, but not large. Also Apples Golden Noble, Ribston Pippin, King of the Pippins, Alfriston, Burchard's Seedling, Warner's King, Blenheim Orange, and Hanwell Souring (Silver Banksian Medal).

A collection of thirty dishes of Pears came from J. W. Melles, Esq., Sewardstone Lodge (gr., Mr. Nicholson). This exhibit contained a very pretty dish of Durondeau (Bronze Banksian Medal).

The finest Pears we have seen this season from an English garden came from Martin Smith, Esq., Hayes Common, Beckenham (gr., Mr. Blick). There were twelve dishes, and the following were the varieties (from pot trees):—Uvedale's St. Germain (3½ oz. each), Pitmaston Duchess (25½ oz.), Doyenné du Comice (21 oz.), Beurré Superfin, Beurré Diel, Conference, Princess, Magnate, Marie Louise, Marie Louise d'Uccle, Conseiller de la Cour, and General Todleben (Silver Banksian Medal).

From Mr. H. Becker, Jersey, came several sorts of Apples for Certificates. Monstrous Incomparable

was described as a very fine looking fruit from the only tree supposed to be in Jersey (on a wall). The variety is supposed to have been brought from France years ago; this was given an Award of Merit. The other varieties were not so fortunate. Mr. E. Molyneux, Swanmore Park Gardens, sent three dishes of Apples, Cox's Orange Pippin, and Mère de Ménage, both very well coloured, and Warner's King (good large fruits), gathered from bushes planted in 1890. Messrs. Paul & Sons, Chesham, had a collection of Apples and Pears, in which we noticed very fine Ribston Pippin, Maux Codlin, Emperor Alexander, and Baumann's Red Winter Reinette (Silver Knightian Medal).

Another very large collection of Apples came from Messrs. Jas. Veitch & Sons, Chelsea. There were 288 dishes, and especially noteworthy were dishes of Peasgood's Nonsuch, Lord Suffield, Emperor Alexander, Tom Putt, Cellini Pippin, Galloway Pippin, New Hawthornden, Histon Seedling, Baumann's Red Reinette, Cockle Pippin, and King Harry, a very nice early dessert variety that has been very popular this year. Also a number of bunches of autumn-bearing varieties of Raspberries in full fruit (Silver-gilt Knightian Medal). Messrs. Jno. Laing & Sons, Forest Hill Nurseries, had 60 dishes of fruits of general excellence. Bismarck Apple was very fine here, also Hollandbury, Mère de Ménage, Peasgood's Nonsuch, Cellini Pippin, and Tom Putt (Silver Banksian Medal). Another collection of 100 dishes of fruit came from Messrs. J. Peed & Sons, Roupell Park Nurseries, Streatham. Among these the finest were Cellini Pippin, Golden Noble, Ribston Pippin, and Dutch Codlin. Also a pretty dish of Doyenné White Pears and Beurré Superfin (Silver Banksian Medal). To show what can be done within the three miles radius of London in the way of fruit culture, Mr. G. T. Bodley, 99, Loughborough Road, sent a few samples of Apples that he had grown in a back garden, of fair quality from such a position.

Mr. George Wythes, Syon House Gardens, obtained a First-class Certificate for a Seedling Melon that he had raised from a cross between Hero of Lockinge and an unnamed variety, also raised at Syon House. Beauty of Syon is a pretty yellow-netted variety, and was described by some of the members of the committee as an exceptionally good-flavoured variety. Mr. A. Bishop, gr. to R. Burrell, Esq., Westley Hall, Bury St. Edmunds, also staged a Seedling Melon.

From the Royal Horticultural Society's Garden, Chiswick, were exhibited Muscat of Hungary, Orez Tirdovanny Grapes.

Mr. J. Bowerman, Hackwood Park Gardens, Basingstoke, showed two dishes of Apples for Certificate. The fruits looked like over-coloured Worcester Pearmain, but were much harder.

A Seedling Apple (Hampton Court Pippin) came from Mr. Robert Morrow, Leominster. Seedling Apples also came from Mr. F. Smith and from Mr. W. Longley, The Mall Nursery, Faversham; and from Messrs. Dickson, Edinburgh.

Messrs. Cooper, Taber & Co., Witham, Essex, sent a box of well-coloured Worcester Pearmain Apple, a dish of Japanese Pole Cucumbers, and some American "Vegetable Peaches" (varieties of Melons that would not be appreciated here) (Accorded a Vote of Thanks).

Messrs. Philip Mayfarth & Co. exhibited fruits and sections of fruits that had been evaporated by their patent machine in the gardens of the Royal Horticultural Society at Chiswick. The results were highly satisfactory, and the samples of rings, parings, cores, &c., of Apples, and the Prunes, Plums, &c., were of the highest order (Silver-gilt Knightian Medal).

A collection of Onions came from Messrs. Jarman & Co., Chard, Somerset, and gained an acknowledgment for their good culture. Mr. J. Willard, Holly Lodge Gardens, Highgate, received a Vote of Thanks for some heads of Silver or Seakale Beet.

Mr. Loach, gr. to the Duke of Northumberland at Albury Park, was awarded a First-class Certificate for a dish of Tomatos (Lady Bird). The fruits were very even, deeply coloured, and appeared to be very prolific.

LECTURE ON CYCADS.—By W. CARRUTHERS, Esq., F.R.S., Keeper of the Botanical Department, British Museum.

Mr. Carruthers commenced his lecture by referring to the difficulty that was first experienced in classifying plants of this order before

any fruits had been seen, and said, that in appearance they had often been described as Palms, and many of them had been mistaken for Tree Ferns, but in reality they were more nearly related to the Pines than to any other family, and they occupy the very base in the classification of flowering plants. The lecturer then proceeded to describe the essential organs, and said that the ovules were quite naked, and that they were fertilised by the direct contact with the pollen grains, and that the absence of stigma, style, and ovary, were the characteristics of the group of flowering plants called Gymnosperms. Mr. Carruthers said that Gymnosperms occupied a very prominent position among the very first dry land vegetation of the globe, and were the remains of an otherwise extinct vegetation. They are now found abundantly in the tropical parts of the world, but in some parts north of the tropics, as in America, and south thereof, as in South Africa and Australia they are also to be found. The genus *Cycas* is most abundant along the borders of the Indian Ocean, and it extends eastwards as far as Tropical Australia, and westwards into Madagascar. In this genus the simple fruit is borne on the margin of the leaves.

Zamia and *Ceratozamia* (between which Mr. Carruthers could see but little difference) have cones whose scales have a linear arrangement, and which meet, but do not overlap at the edges, and the fruits are borne on the inner surface of the petalate scales. They come chiefly from the tropical regions of the New World, but three species are found in Florida. *Ceratozamia* in the New World were peculiar, in that they had cones composed of scales arranged in a linear manner, while, on the other hand, the cones of the Old World genera have scales which are spirally arranged.

Encephalartos, a well-known South African genus, is useful and decorative in large stoves in this country, has spirally-arranged scales. They are found chiefly in the extreme south of Africa.

Macrozamia, the lecturer stated, was found in Australia, had petalate scales, the tips of which are directed upwards.

Dioon (the principal species of which was *D. edule*) were found in Mexico. The cones were composed of flat imbricated scales, and this kind of scales Mr. Carruthers said was found in America, S. Africa, and in Australia.

Stangeria, a monotypic genus, with foliage like a Fern, and very unlike in appearance to the other Cycads, was a native of South-east Africa.

In conclusion, the lecturer said he would not go into the question of culture, but would merely warn amateurs having these plants under their care that they form a large amount of pith in the stems, and that after remaining for a long time dormant (even for years), they would sometimes spring into fresh growth without any apparent reason; it was, therefore, unwise to throw stems away, so long as they were not quite dead.

Dr. Masters (who occupied the chair), alluded to the geological history of the plants, and said that he was quite in sympathy with the lecturer in his surprise that members of the Cycad family were not more widely grown for decorative purposes than they were.

Mr. W. Watson, of the Royal Gardens, Kew, gave a few hints as to general culture, and also recited an interesting case of the wonderful vitality possessed by the old stem of these plants. The plant was *Macrozamia Moorei*, and a stem about 9 feet long, was imported, which remained in the Palm-house for years, without growing, and when looked at, the lower part of the stem was found to be rotten, and the top was then cut off, and put in as a gigantic cutting, and it is now a thriving plant.

In illustration of the lecture the authorities of the Royal Gardens, Kew, sent cones of *Dioon edule* (female), *D. spinulosum* (male), *Ceratozamia mexicana* (female), *Zamia muricata* (female), *Z. Skinneri* (male), *Macrozamia spiralis* (male), *Encephalartos villosus* (female), *E. Altensteinii* (male), *E. caffer* (male), as well as leaves of all the genera of Cycadae.

FUNGUS FORAYS, 1892.

In bygone days the reports of fungus forays were long and enthusiastic, not wholly lacking in adventure, nor wanting in interest. Of late years, the record has been written under a feeling of depression and disappointment. Those of us who remember the excursions of twenty years, or even of ten years ago, cannot fail to recognise in the field days of the past three or four years, only the ghosts and shadows

of the "long ago." It is a question of fact, and not of feeling, that an immense change has taken place. First and foremost in the great dearth of the larger fungi, those of the Mushroom kind, everywhere. To whatever causes we may attribute this, the fact still remains, that woods which in the days of our remembrance, literally swarmed with toadstools, are now comparatively bare. Then it was impossible to carry away in our baskets one-half of the good things met with, and the baskets were big ones, to adorn the tables for the annual exhibition. Now, it becomes incumbent to secure everything that is met with, good, bad, or indifferent, in order to make up an exhibition at all. Then it was that tables to the length of 150 feet could be closely packed with the spoils of two or three days; but now, a table of 10 or 12 feet in length is all sufficient. When we are compelled to confess that, in excursions extending over ten days, we only saw one juvenile specimen of the ubiquitous *Agaricus mellens*, it will be sufficient to astonish the old marauders of 1872 to 1882, and to justify us in our lament for the good old times.

The Yorkshire Naturalists Union held a fungus foray in the neighbourhood of Malton on September 13, 14, and 15, in localities to which, under ordinary conditions, no exception could be taken; but, unfortunately, although there was no lack of walking, the results were far from adequate, common species were conspicuously absent, and, in all cases, the number of individuals was remarkably small. It is not unusual, in such cases, to meet with one or two individuals of rare species, or at least of species having considerable interest, and such was the case on the present occasion. We were surprised to see that splendid edible agaric, which has hitherto been confined to about three British localities, *Agaricus (Psalliota) elvensis*, in Yorkshire, and also some few others which had not previously been recorded for the county, including a large species of the sub-genus *Inocybe*, allied to *Agaricus scaber*, which could not be referred to any described species, or, at any rate, only tentatively to a species described by Britzelmayer, and not previously known in Britain. There was considerable local interest in the fungus-hunt, and it was unfortunate that the exhibition could not be made more worthy of the occasion, notwithstanding the praiseworthy efforts of the several local naturalists who, many of them, undertook considerable journeys to be present.

In the following week, the Woolhope Field Club held their annual meetings at Hereford, Tuesday, September 20, was devoted to Whitcliff Woods, near Ludlow, an old hunting-ground of the Club; but on this occasion the persistent downpour of rain throughout the day rendered the gathering of fungi beneath the shelter of umbrellas an unenviable occupation, and entailed subsequent results not quite pleasurable to such as were not impervious. The Thursday's excursion in the woods of Dinmore was favoured with fair weather, and the collection made was much better than in the same locality two years ago. Somewhere about a dozen species, not recorded before for the county of Hereford, will have to be added to the flora of Herefordshire. One of the most noteworthy additions was *Agaricus (Stropharia) Percevalii*, only found previously near Morpeth. At the exhibition were to be found an interesting collection of fungi sent by H. Spencer Perceval, Esq., from the last-named locality, and a smaller collection made by T. Howse, Esq., in Surrey, amongst the latter being *Agaricus (Tricholoma) circumtextus*, for which only one locality had previously been known. In neither of the above cases of fungus forays held this year could sufficient edible fungi be collected to furnish the table with a dish, except, perhaps, of the Horse Mushroom, *Agaricus arvensis*, of which about six specimens were found. With such a record we, who remember better days, are apt to sigh for a return of "the good old times."
M. C. Cooke.

NOTTINGHAM ST. ANN'S FLORAL AND HORTICULTURAL.

OCTOBER 6.—The last of this year's series of flower shows in connection with this Society, was held on the above date. The members have competed during the season for points, as well as for money prizes, and these points will now be added up, and a Gold Medal presented to the highest competitor, whilst the 2nd and 3rd will receive a Silver Medal and a Bronze Medal respectively. The series have ended most successfully, and in this last show the entries were numerous, and the quality of the exhibits was even higher than at previous exhibitions. There were classes for plants, *Chrysanthemums*, *Dahlia*s, *Roses*, cut flowers, *Tomatoes*, vegetables, &c.

THE ROSERY.

OCTOBER IN THE ROSE GARDEN.

This month is, or ought to be, a busy one with all those who wish to have their Rose garden a thing of beauty next year. Alterations have to be made, selections made as to what should be eliminated, and what added, and many other little matters set on foot. It may not then be out of place to put on record a few things which may be helpful to the Rose grower, whether he be an exhibitor or not. One hears a great deal of the enmities of exhibitors, and how their gardens are spoiled for the sake of the exhibition table, and these charges are to some extent true. It is a shock to one's nerves to go into a Rose garden and see the beds covered thick with manure, caps, parasols, and all sorts of contrivances scattered all over, but that need not be done—while, at the same time, the principles on which the exhibitor acts may be the very best for the non-exhibitor, who loves his *Roses*. For instance, exception is taken to the manner in which *Roses* are pruned, and so restricted in their growth that they are not allowed to grow more naturally, but I know no way in which *Roses* look so well as when they are grown as above, and carefully treated. To look over a garden so managed as was that of that true lover of the Rose, the late Mr. George Baker, of Reigate, was indeed a treat, and I feel sure it is sound advice to recommend all who wish to have really good *Roses*, to adopt that exhibitor's plan of growing dwarfs, and of treating them in the same way that he did, although they may never have the slightest intention of placing a box of *Roses* on the exhibition table.

I have in my mind in writing these notes not the large growers, who know more about these matters than I do, but those who are desirous of having the comparatively few *Roses* they do grow in as high a state of perfection as possible, and for such persons October comes with its many questions to be solved, as a rather serious matter. Their object may be either to make new plantations, or substitute some new plants for others they are anxious to discard. In the case of the former, it will be necessary to dig the ground well, or to trench it, provided the subsoil is fairly good. I have known ground trenched to the manifest injury of the garden, for it brought up an unhealthy soil to the surface, which was not got rid of for years. For both of these operations there are one or two things to be remembered. One is, not to allow any manure to come in contact with the roots of the early-planted *Roses*. Anyone who has noticed what takes place when plants have been laid in for a short time, will recollect the small white roots which are emitted from the older roots. Now, if these rootlets come into contact with the manure, they will find it too strong for them, and they become brown, and make no progress. Therefore, when a new piece of ground has to be trenched, the manure is laid at the bottom of the trench, so that it is some time before the new roots get to it. In the case of individual plants in beds, it is better to make a hole where the Rose is to be planted, and fill it up with fresh sweet fibrous loam from the top spit of a pasture, which has been laid up for a few months; failing this, any good sweet soil will answer. When the soil is too heavy, it may be lightened with leaf-mould; but it should always be borne in mind that the soil which the *Rose* loves is a rich, tolerably stiff loam, not clay, although it may be very near to it in its texture. In this sweet soil the young rootlets will revel, and by the time the manure reaches them, either from the trench or from the mulching, they will be prepared to absorb all its valuable properties without injury. Another reason for not applying manure close to the plants is, that you avoid thereby encouraging fungi, which are apt to considerably damage the roots.

Another necessary point to observe in planting is that of planting firmly. Of course, where standards are planted, stakes must be used to keep them firm;

but whether it be standards or dwarfs, the firm planting is a great point. The hole should be opened pretty wide, and the roots spread out evenly round; the soil should then be placed upon them, and when the roots are covered, that should be stamped down, holding the plant in one hand, and then the remainder of the soil should be added, and again pressed firmly down. If the shoots of the early-planted *Rose* are long, it may be advisable to place a short stake to keep all firm, for I am sure nothing is more injurious to the well-being of the plant than its being "wobbled" about by the wind; then again, in all cases, no matter what the stock may be, they should be planted so that the point where the bud was inserted, should be at least 2 inches below the surface, this secures the bud from drying up; and, moreover, after a little while, roots are emitted from the scion itself, and so the plant becomes doubly cared for, having the roots of the stock and its own roots to supply it with nourishment. This is the reason why, although we hear to the contrary, budded *Roses* are so long lived. I have two dwarf plants on the *Manetti* of *Souvenir de la Malmaison*, which have been in my possession for forty years at least.

The question of what to plant, and on what stock to have them, is a somewhat complex one; there seemed at one time as if the *Manetti* was to be ruled out of court, but it is asserting itself again, and on light soil, I believe, it is still the most desirable stock; on really good *Rose*-soils, such as the soft nutritious loams of Hertfordshire, the wild Briar, or the seedling, will hold its own; while for the Tea *Rose* there can be little doubt that the *Manetti* is not suited, the Briar standard, or half standard, and the seedling Briar are just suited for its wants, the *Manetti* is too vigorous and too early.

With regard to which varieties are to be selected to fill the vacancies in the beds, or to be used in the formation of new beds, there are several things to be considered, as the advice to be given will differ according to the necessities of the grower, i.e., whether he be an exhibitor or not. The former will look out for new varieties, or such flowers as will stand him in good stead on the exhibition table; the latter will consider best which may ornament his garden. I shall bear the latter in mind, and, although the *Roses* hereafter mentioned are exhibition *Roses*, they are none the less suitable for garden decoration. There are, for instance, some varieties which, although very lovely, are yet of such indifferent habit that they bring nothing but disappointment. Take, for example, those most lovely dark *Roses*, *Xavier Olibo*, *Reynolds Hole*, and *Louis van Houtte*: one often hears the statement concerning them that they are only good on maidens, implying that you must not look for them to bear more than one year, or at least to live so as to give good blooms. Such a flower also is *Horace Vernet*, and it was remarked as a noticeable fact of a grand bloom of this fine variety exhibited by Mr. E. B. Lindsell at Earl's Court that it was from a cutback. I would not, therefore, advise such *Roses*. Then again there are certain *Roses* which are frightfully subject to mildew, and which not only are extremely subject themselves, and disfigure the beds where they are planted, but also are likely to spread the fungus, of such I mention *Abel Carrière*, *Hier Majesty*, *Jean Soupert* (syn. *Great Mogul*); then, again, there are *Roses* both amongst the Hybrid *Perpetuals* and *Teas*, fair-weather *Roses*, such as *Jean Ducher*, *Marie Guillot*, and *Mons. Noman*; implying that when we have a wet season the blooms become glued together, and rot on the shoots, not merely disappointing our expectations as to flowers, but giving the plant a most unsightly appearance; and there being so many beautiful *Roses* in the same strains of colour, I do not think it is worth while to recommend any moderate growers, for this term implies weakness of constitution. Then there are other *Roses* which are called uncertain; that is, you may now and then have a good bloom, but they are few and far between, such, for instance, as *Boildieu*, *Henri Ledecbaux*, and *Marie Rady*, beautiful when you get them, but

the when is a very uncertain quantity. I am quite aware that there will be some growers who will perhaps say of some of the Roses I have taken exception to, "Oh! that is very good with me." Yes, possibly, for Roses have their idiosyncrasies. Thus, in the garden of Mr. Fowler at Taunton, where Tea Roses do well, he can never, although the plants grow well, get a presentable bloom from Rubens or Anna Olivier, easily grown varieties, although he succeeds admirably with Comtesse de Nadaillac and Souvenir d'Elise, and such peculiarities may be seen in other places. I do not know anything to account for them. I would recommend the following:—

Alfred Colomb: this is so often like Marie Baumann, that it has been suggested that they should be bracketed together, but at other times it is quite distinct; Alfred K. Williams, exquisitely formed, very early, and a good autumnal bloomer; Baroness Rothschild, a long-established favourite—unhappily, it has no perfume; Beauty of Waltham, Camille Bernardin, Captain Christy; Charles Lefebvre, a grand old Rose, and I very much question if there is anything to surpass it—it is not so vigorous with many as one could wish, but I have seen it in splendid vigour at Mr. Hall's, of Larchwood, and in many other places; I believe it to be one of those Roses which the Manetti suits best. Sir Rowland Hill is a sport from this, which it too often shows by "harking back" to the type; Comtesse d'Oxford, Comte Raimbaud—I do not like to leave this out, although I have never grown it, but it has been shown beautifully, and is described as a vigorous grower. Countess of Rosebery, Devienne Lamy, Dr. Andry, very bright, very vigorous in growth, and abundant bloomer; Duke of Edinburgh, a fine vigorous grower and brilliant Rose, blooming well a second time; Earl of Dufferin, a very bright and beautiful Rose; Elie Morel; General Jacqueminot—although this Rose has been out so many years, there are times when there is nothing to beat it, so brilliant and beautiful is it. Prince Arthur, I look upon as a strain of this fine flower; Gustave Piganeau is a new Rose, of large size, and apparently good habit, but I think it is too early to judge it; it is not the style of Rose that I care for, but it will much please those who look for size; Heinrich Schultheiss, vigorous and free; Lady Helen Stewart, very bright; Marie Finger, Madame Gabrielle Luizet, a very lovely early-blooming Rose, hardly perpetual, although I have always had blooms of it in autumn; Madame George Schwartz, Madame Lacharme, a very full white Rose; Madame Victor Verdier, Magna Charta, Marguerite de St. Amand, Marie Baumann, perhaps, after all, the most beautiful Rose we have in its class—sometimes it seems difficult to grow it well, while at other times, it is very vigorous; Marquise de Castellane, Merveille de Lyon, Ferdinand de Lesseps, Madame Joseph Desbois, a good light-coloured Rose; Jules Margottin, an old but very delightful garden Rose very sweet-scented, and free-flowering; La France—there is no need to say anything about this universal favourite; Marie Verdier, Mrs. John Laing, a grand Rose, the best of Mr. Bennett's seedlings, very free, and an abundant autumn bloomer; Paul Neyron, very large, but valuable in autumn, though its first flowers are coarse; Prince Camilla de Rohan, one of the best of our dark Roses; its constitution is better than many of the same colour; Rosieriste Jacobs, in flower; this seems to be identical with the Duke of Wellington, but it is a better grower; Sénateur Vaisse, an old Rose, sent out upwards of thirty years ago, but still first-rate; Star of Waltham, a fine Rose; Sultan of Zanzibar, a good dark Rose; Suzanne-Marie Rodocanachi, beautiful soft cerise colour; Ulrich Brunner, a large fine Rose, fine habit; Victor Hugo, a beautiful dark Rose; Vicountess Folkestone, a large, fine, and very effective garden Rose; Violette Bouyer, a very beautiful white Rose, with a very slight tint of pink; W. E. Bennett, very fine and bright. I will reserve the Tea Roses for a short notice in a future number. *Wild Rose.*

TREES AND SHRUBS.

INDIGOFERA GERARDIANA.

This is a distinct and useful leguminous shrub. It grows wild in the Western Himalayas at elevations varying from 2000 feet to 6000 feet above sea-level. Round London it grows with freedom in the open border, but farther north it requires some protection, as during severe winters its long wiry shoots are frequently cut to the ground-line; but with the return of spring new growths are made from the old stock, and are freely furnished with light green Acacia-like leaves. The bright rosy-pink flowers are carried in great profusion from the axils of the leaves on spikes several inches long. Where not sufficiently hardy to withstand the winters in the open, it well repays the trouble of planting it against a wall, making fast the principal growths thereto, and allowing the smaller shoots to spread at will; they will then assume a very graceful appearance, and in July and August its brightly-coloured Pea-shaped blossoms will be seen to advantage. In such a position it attains a height of 10 to 12 feet, but in the open border it is seldom seen more than half that height. Besides being of such a floriferous nature, it is also an ornamental shrub. Like a great number of the Leguminosæ, it thrives well in hot dry sandy soils. To increase the stock, select young growths about 3 or 4 inches long; these may be taken off with a sharp knife any time in the months of August and September, at which time the wood will be moderately firm. Dibble the cuttings into light peat soil in pots which have been well crocked, and when completed, give a good watering with a fine-rose can, and plunge the pots in Cocoa-nut fibre in close propagating-cases, with a bottom-heat of about 65° to 70°. In a couple of weeks or so roots will have formed, and they can then with safety be taken out of the cases and hardened off, ready for standing in cold frames for the winter, and the following spring they should be planted out in the nursery ground.

A very good companion to the above is *I. coronilæfolia*, sometimes confused with *I. Gerardiana*, upon which species it is a decided improvement; it flowers a week or ten days later. Its flower-spikes are bigger than the first-named, and the colour of its flowers of a deeper hue. It possesses a very strong constitution, and thrives well under the same treatment as *I. Gerardiana*. *H.*

TRADE NOTICE.

THE partnership which has existed between Mr. G. H. BROUGHAM GLASIER and HENRY J. DOWDEN, Fellow of the Surveyors' Institution, under the title of MESSRS. GLASIER & SONS, of 6, Spring Gardens, Charing Cross, having ceased by effluxion of time, the latter gentleman informs the public that he will continue in practice on his own account, at 314, Regent Street, Portland Place, W.

Obituary.

WILLIAM HEATH.—We regret to announce the death of Mr. William Heath, the head of the well-known firm of Heath & Son, of the Royal Exotic Nurseries, Cheltenham. Mr. Heath, who had been long resident in that town, and whose services in various municipal capacities were greatly valued by his fellow townsmen, was a successful man of business, and a constant exhibitor of plants at west country shows, and sometimes in London and other cities. The deceased was an excellent cultivator of stove plants and Dahlias, his last prize, a 1st, at the Cheltenham show, being taken with twenty-four blooms against eight competitors. In the years from 1840 to 1850 he had a good record as a grower of all kinds of florists' flowers, particularly Carnations. The nursery at Cheltenham was started by

him in 1830. Mr. Heath, who, with another guardian of the poor, was visiting the out-paupers in the country district on September 28, was thrown from his waggonette. He died on Saturday, October 8, at the age of eighty-two years.

THE WEATHER.

[By the term "accumulated temperature" is meant the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named; and this combined result is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

The districts indicated by number in the first column are the following:—

0, Scotland, N. Principal Wheat-producing Districts—1, Scotland, E.; 2, England, N.E.; 3, England, E.; 4, Midland Counties; 5, England, S. Principal Grazing, &c., Districts—6, Scotland, W.; 7, England, N.W.; 8, England, S.W.; 9, Ireland, N.; 10, Ireland, S.; (* Channel Islands.)

THE PAST WEEK.

THE following summary record of the weather for the week ending October 15, is furnished from the Meteorological Office:—

"The weather although fair for a day or two in the middle of the period, was mostly wet and unsettled; especially in the north and east of England, were exceedingly heavy falls of rain occurred between the 13th and 15th. Lightning was seen at some of our southern stations on the night of the 14th.

"The temperature was everywhere below the mean, the deficit amounting to only 2° or 3° in most districts, but reaching 4° in 'England, S.W.,' and 5° in 'Ireland, S.' The highest readings, which were observed at times varying greatly in the different districts, ranged from 54° in 'England, N.E.,' and 55° in 'Scotland, N.,' 'England, N.W.,' and 'Ireland, N.,' to 60° in 'England, S.' and the 'Channel Islands.' The lowest readings were registered mostly about the middle of the week, when the thermometer fell to 32° or less in all districts, excepting 'Scotland, N.,' 'England, N.E.,' and the 'Channel Islands.' In 'England, N.W.,' 'England, S.W.,' and 'Ireland, N.' the minimum readings were as low as 28°.

"The rainfall was less than the mean in Ireland, Scotland, and the southern parts of England, but a trifle more than the mean in the Channel Islands, and considerably in excess over the north and east of England. In 'England, E.' the amount was more than twice, and in 'England, N.E.' more than three times the average.

"The bright sunshine was in excess of the mean over the central and southern parts of England, as well as in the west of Scotland and the south of Ireland, but elsewhere there was a slight deficiency. The percentage of the possible amount of duration ranged from 14 in 'Scotland, E.,' and 20 in 'Scotland, N.,' to 35 in 'England, S.' and 38 in 'England, S.W.' and 'Ireland, S.'"

MARKETS.

COVENT GARDEN, October 20.

[We cannot accept any editorial responsibility for the sub-joined reports. They are furnished to us regularly every Thursday, by the kindness of several of the principal salesmen, who revise the list, and who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the supply in the market, and the demand; and they fluctuate, not only from day to day, but often several times in one day, Ed.]

TRADE still quiet, with fair supplies. James Webber, Wholesale Apple Market.

POTATOS.

For best samples the trade still continues to improve. Prices remain about same as last quotations. J. B. Thomas.

SEEDS.

LONDON: Oct. 19.—Messrs. John Shaw & Sons, Seed Merchants, of Great Maze Pond, Borough, London, S.E., write that more attention is now being given to Red Clover seed. The prices asked for French seed are this season extremely high. Alsike and White are just now neglected. Trefoil promises to prove a short crop. The high figures demanded for Rye-grasses check business. Winter Tares realise full prices. There is no change in Rye. Canary-seed keeps strong. Hempseed is steady at the late rise. Some fine new German Rubsen is now obtainable at tempting quotations. Bird Millet points upwards. Blue Peas maintain former terms. For Haricots the trade improves. Buckwheat and Linseed are steady.

POTATOS.

SPITALFIELDS: Oct. 18.—Quotations:—Magnums, 45s. to 60s.; Sutton's Early Regents, 50s. to 60s.; Imperators, 60s. to 65s.; Beauty of Hebron, 50s. to 65s.; Early Rose, 45s. to 50s.; Snowdrops, 60s. to 80s.; Reading Wonder, 65s. to 70s.; Bruce Magnums, 60s. to 65s.; Sutton's Abundance, 60s. to 65s. per ton.

BOROUGH: Oct. 18.—Quotations:—English Magnums, 40s. to 60s.; Hebrons, 40s. to 60s.; Snowdrops, 50s. to 65s. per ton.

FRUITS AND VEGETABLES.

SPITALFIELDS: Oct. 18.—Quotations:—English Apples, 2s. 3d. to 6s. 6d. per bushel; American do., 10s. to 17s. per barrel; Pears, 2s. to 4s. 6d.; Prunes, 4s. to 4s. 6d.; Damsons, 3s. 6d. to 4s. 6d.; Bullaces, 2s. to 2s. 6d. per half-sieve; English Tomatos, 4s. to 5s. per peck; foreign do., 1s. to 2s. per box; Savoys, 2s. 6d. to 5s.; Cabbages, 4s. to 6s.; Collards, 2s. 6d. to 5s.; Cauliflowers, 3s. to 7s.; Marrows, 3s. 6d. to 8s. per tally; Spinach, 1s. 6d. to 2s. 6d.; Scarlet Beans, 2s. 6d. to 3s.; Beetroot, 1s. 6d. to 2s. 6d. per bushel; Brussels Sprouts, 2s. to 2s. 3d. per half-sieve; Turnips, 2s. to 2s. 6d. per bag; do., 2s. to 2s. 6d.; Carrots, 1s. 6d. to 3s.; Onions, 3s. 6d. to 4s. 6d.; Parsley, 1s. 6d. to 2s. 6d. per dozen bunches; Mint, 1s. 6d. to 2s. 6d. per dozen bunches; Endive, 6d. to 1s.; Cabbage Lettuces, 3d. to 6d.; Frame Cucumbers, 2s. to 3s. per dozen; Celery, 10d. to 1s.; Horseradish, 1s. to 1s. 2d. per bundle; Spanish Onions, 5s. 3d. to 6s. per case; Dutch do., 4s. 6d. to 6s. 6d.; Belgian do., 3s. 9d. to 5s. 6d. bag of 110 lb.; Cos Lettuce, 4d. to 1s. per score; Carrots, 2s. to 50s. per ton.

BOROUGH: Oct. 18.—Quotations:—Cabbages, 3s. to 4s.; Marrows, 3s. 6d. to 4s. per tally; Cauliflowers, 1s. to 1s. 6d. per dozen; Brussels Sprouts, 2s. to 2s. 6d. per half-sieve; Lettuces, 6d. to 1s. per score; Carrots, 2s. 6d.; Turnips, 1s. 6d.; Parsley, 1s. 6d. per dozen bunches; English Onions, 4s. to 4s. 6d. per cwt.; Horseradish, 2s. to 2s. 3d.; foreign do., 1s. 6d. to 1s. 9d. per bundle; English Apples, 2s. 6d. to 10s. per bushel.

STRATFORD: Oct. 19.—There has been an excellent supply of all kinds of produce at this market during the past week, for which a brisk trade was done as under:—Cabbages, 3s. to 5s. per tally; Savoys, 3s. 6d. to 5s. 6d.; Collards, 2s. to 2s. 6d. per dozen; Cauliflowers, 1s. 6d. to 1s. 9d. per dozen; do., 3s. to 6s. per tally; Turnips, 1s. 6d. to 2s. 6d. per dozen bunches; do., 4s. to 50s. per ton; Carrots, household, 30s. to 40s. do.; do., cattle feeding, 2s. to 30s. do.; Parsnips, 60s. to 65s. do.; Mangolds, 15s. to 20s. do.; Swedes, 20s. 6d. to 28s. 6d. do.; Onions, English, 6s. per bag; do., Dutch, 4s. 6d. to 5s. do.; Apples, English, 2s. to 5s. per bushel; do. American, 12s. to 14s. per barrel; Cucumbers, 1s. to 1s. 3d. per dozen.

FARRINGTON: Oct. 20.—Quotations:—Apples, King Pippins and Wellingtons, 4s. per bushel; Blenheim, 4s. 6d. do.; English Onions, 110s. to 120s. per ton; Belgian do., 100s. do.; Spanish do., 6s. 6d. per case; Carrots, 50s. per ton; Parsnips, 65s. to 70s. do.; Celery, 10s. per dozen rolls.

HAY.

Averages.—The following are the averages of the prices at the metropolitan markets during the past week:—Clover, prime, 80s. to 115s.; do., inferior, 46s. to 75s.; Hay, best, 60s. to 110s.; do., inferior, 26s. to 50s.; and Straw, 26s. to 41s. per load.

CORN.

Averages.—Official statement of the average prices of British corn, imperial measure (bushel) for the week ending October 15, and for the corresponding period last year:—1892: Wheat, 28s. 1d.; Barley, 27s. 6d.; Oats, 17s. 8d. 1891: Wheat, 34s. 9d.; Barley, 29s. 6d.; Oats, 18s. 10d.

NOTICES TO CORRESPONDENTS.

PHOTOGRAPHS, DRAWINGS, OR SPECIMENS.—We shall be pleased to receive from our correspondents notes relating to interesting Gardens, together with specimens or illustrations of interesting Plants. Although circumstances prevent us in all cases from reproducing them, we are nevertheless glad to receive them, and as far as possible to utilise them for the benefit of our readers.

APPLE: R. C. D. Send better specimens.

BOOKS: Amicus: The last edition was in 1884; it is still the most complete in the account of the natural orders, but the physiological portion is somewhat out of date.

CATTELEYA LABIATA AND C. WAROCQUIANA: J. J. The second is a variety of the first-named species. If distinct species are meant, you could scarcely exhibit them as being "distinct" (species) of Orchids.

CORRECTIONS.—Back Numbers of this Journal. All numbers are out of print up to 1887, but not inclusive of that year, as was stated in error in our last. In our last issue, NAMES OF PLANTS, No. 2, W. Naish, the plant-name Nerine, was accidentally spelled Nermi.

CHRYSANTHEMUM: W. G. Yes, a sport; there are many as good.

CONTRACT TO SUPPLY ROSE STOCKS: W. D. Consult a solicitor. It is a nice point.

CUCUMBER ROOTS: H. D. A bad case of eel-worm attacking the roots. Figures and descriptions have been repeatedly given in our columns. Burn the plants, turn out the soil, and start afresh with new soil.

ENDOSMOMETER: C. G. B. A funnel and a bit of membrane (bladder) stripped of its outer covering to tie over the nozzle, and a graduated scale are all that are wanted. You might make one.

FRUIT SALESMEN IN COVENT GARDEN MARKET: W. L. We cannot undertake to recommend salesmen. Consult our advertising columns.

INGA SEEDS: G. A. M. Seeds of Guizotia oleifera, a Composite, like a small Sunflower.

INSECT: C. A. P. The insect you send are millipedes (fig. 78 (4) below), often confused with wireworms, and for your purpose equally objectionable. It has nothing to do with any fly. Burn all the affected plants, turn out the soil and get fresh soil, carefully examining it to see that it does not contain some

FIG. 78.—MILLIPEDES.

more of your enemies. If your plants are in pots you can trap some of the insects with pieces of Potato, Carrot, &c., and having trapped them, immolate them. Only beware of the anti-vivisectionists!—H. A. B. See the answer to "W. H. W." on p. 474, of our last issue. It is evidently a beetle.

NAMES OF FRUIT: No. 7. 1, Lady Henniker; 2, Cellini; 3, not recognised; 4, Mitchell Crab; 5, not recognised; 6, Manka Codlin; 7, Louise Bonne.—J. Ratcliffe. 1, Striped Beefing; 2, Belle et Bonne; 3, Dutch Mignonne; 4, Northern Greening; 5, Fearn's Pippin.—Geo. Jones. 1, Bess Pool; 2, Fearn's Pippin; 3, Cox's Orange Pippin.—W. M. 1, Pitmaaton Duchess; 2, Beurré Bachelier.—A. B. 1, King of the Pippins; 2, Bedfordshire Foundling; 3, not recognised; 4, Ribston Pippin; 5, Cluster Golden Pippin.—H. & S. Apple Tower of Glamia.—J. W. 1, Lamb Abbey Pearmain; 2, Warner's King; 3, Golden Reinette; 4, Pearson's Plate; 5, Round Winter Nonsuch; 6, Scarlet Nonpareil; 7, Hoary Morning; 8, Grange's Pearmain. Pears next week.—G. Abbey. 1, Emille d'Heyat; 2, Glou Morceau; 3, Urbaniste; 4, Knight's Monarch.—J. A. L. 1, Round Winter Nonsuch; 2, Mère de Ménage; 3, not recognised; 4, Striped Beefing; 5, Scarlet Nonpareil; 6, not recognised.—J. H. J. Apple Mère de Ménage; Pear, too far gone.—Totnor. 1, too ripe; 2, Shobden Court; 3, Beurré Hardy; 4, Beurré de Capiaumont; 5, Vicar of Winkfield; 6, General Todleben; 7, Louise Bonne.—Mahalm Brodie. Pears: 1, Marie Louise d'Uccle; 2, Thomsons; 3, Vicar of Winkfield; 4, Urbaniste; 6, Crème de Flandres. Apples: 5, Yorkshire Greening; 7, Minchall Crab; 8, Emperor Alexander; 9, not recognised; 10, Warner's King? 11, Cox's Orange Pippin; 12, Cox's Pomona.

NAMES OF PLANTS: J. B. Stone. 1, Cataetum sp. (next week); 2, Cataetum purum; 3, C. tridentatum; 4, Epidendrum nocturnum.—Davallia. 1, Davallia bullata; 2, D. Tyermanni; 3, D. canariensis, Gymnogramma chrysophylla, Selaginella Mertensii, Pteris (Doryopteris) palmata, Oncidium flexuosum.—T. S. Helianthus multiflorus, Composite; Physalis Alkekengi, Solanad; Narcissus italicus.—Nomen. An? Aralia; near to chinensis. We cannot tell for certain from the withered bit sent.—Anderson. 1, not recognised;

2, Pittosporum tenuifolium; 3, Coccoloba platycladon; 4 and 5, Farfugium grande (Composite).—T. J. & Sons, Griaelinia littoralis; excellent for sea-side (Cornoceæ), New Zealand.—Reginald, Hemp, Cannabina sativa, Urticaceæ.—Head Gardener, Carduus benedictus, the Virgin's Thistle (Composite); Nicotiana glauca (Solanad).—A. W. 1, Picea excelsa variety; 2, P. orientalis; 3, P. Alcockiana; 4, Pinus monticola; 5, an Ash—cannot tell which from scrap sent; 6, Thuja orientalis var.; 7, Juniper—impossible to name; 8, a Juniper—cannot be recognised from a scrap; 9, Spiræa Fortunei; 10, Ilex microphylla; 11, Cornus tricolor.—E. M. C. If you could see the flower as it reached us, you would not wonder that we cannot name it.—C. H. Ferns, next week; 6, Euphorbia splendens.—A. B. Pyrethrum uliginosum (Composite).—Harris. Next week.—Brun (Lyons). Rosa. No letter received at present.—W. O. Cattleya granulosa. Send all communications to the editor, and not to any member of the staff individually.—J. C. 1, Cotyledon—send when in bloom; 2, Pilea muscosa; 3, Begonia sp.; 4, Callicarpa purpurea; 5, Croton; we cannot undertake to name these plants—send to a nurseryman; 6, Bromeliad—send when in flower; 7, Pellionia Daveauiana.

NURSERY STOCK: W. B. The time allowed for clearing land of the saleable stock varies in different parts of the country. Twelve months is a reasonable and the more generally adopted limit. We have not before heard of two years being granted.

PROFITABLE SALE OF CUT BLOOMS, &c.: Profit. We are unable to afford you any other information than that which will be found in our pages in answer to similar enquiries. One man will starve where another succeeds.

SEEDLING PINKS: B. L. Very good for borders, but hardly suitable for pot culture. A purple self. What is the parentage?

SHRUBS: C. P. If the shrubs are part of your trade-stock you can remove them, and that too at the suitable time for removing them. Some landlords will grant a whole year in which to effect the removal of growing stock. If they are not saleable stock you cannot remove them if the landlord objects, nor can you make him pay you for them.

LATE PRODUCTS OF THE GARDEN: T. W. The Peas are good, but Ne Plus Ultra would be better still. The Perfect Marrow must not be despised as a late bearer. It is not at all unusual for Strawberries to bear in the autumn. Forced plants planted out after being carefully hardened off frequently so do if the season is warm. There are several varieties of Raspberries which are autumn bearers.

WASTE IN THE CROPS OF PEACHES AND NECTARINES: P. K. Many causes lead to loss of fruit which only those on the spot can detect. We may specify a few of the more common of these. The crop arriving at the ripening stage all at once or nearly so; the depredation of squirrels, wasps, hornets, flies, earwigs, and sometimes of blackbirds and thrushes. The pilfering of the fruit by persons having access to the garden, and the neglect to remove projecting nails and studs from the neighbourhood of the fruit, whereby wounds are made in the skin, and decay set up. When the fruits are gathered daily as they approach ripeness, and placed in a cool dry place, the loss from decay need not exceed one in a dozen, if the consumption of the fruit keep pace with its ripening.

COMMUNICATIONS RECEIVED.—W. B. G.—Comte de K.—D. M.—R. D.—J. D.—F. v. D.—Dr. Goetz, Griefswald.—Canon E.—H. W.—H. J. V.—H. W. W.—M. H., Melbourne.—Baron von Mueller, Melbourne.—J. F. J., Brooklyn.—D.  Nurseries:—BILLING ROAD.
 Telegraphic Address:—"QUICK, NORTHAMPTON."

VICTOR POTATOS

(SHARPE'S).

This favourite first early Potato, suitable for any Garden, indispensable for Forcing and Early Borders, and likely to take the first rank amongst first earlies for market use. Quality and yield all that could be desired. One well-known market grower has this year had a yield of 15 tons per acre on a large acreage. London and Manchester salesmen speak highly of their quality, and report that Victors will keep their bloom and have a fresh appearance after being in the market some days, when other early Potatoes have become discoloured and unsaleable.

The stock we offer is the true yellow-fleshed variety and not the white variety, which is often substituted.

Price per cwt. and ton. State requirements to

W. W. JOHNSON & SON,
 Seed Growers and Merchants, Boston, Lincolnshire.

THE COLORADO BLUE SPRUCE,

PICEA PUNGENS GLAUCA.

Handsome specimens, 2, 3, 4, 5, and 6 feet high. These are all of the *Bluest* type, and undoubtedly the finest Plants in Commerce. They are all Seedlings, the plants usually met with being grafted on the Common Spruce Fir.

FIXED.

THE IMPROVED GARDEN GULLY
(VINCE'S PATENT).

This useful invention is a great improvement on the ordinary Garden Grating, and is especially suitable for hilly walks and drives. As they never get stopped by rubbish or sand they effectually prevent the washing away of the gravel in heavy storms, and they save half the labour in cleaning out the cesspools. The prices are:—

6-in., 1s. 6d.; 8-in., 2s.; 10-in., 3s.; 12-in., 6s. 6d.; 15-in., 8s.
(The larger sizes are very strong for carriage drives.)

Full Particulars on application. Testimonials:—

From Mr. J. WILLARD, Head Gardener to the BARONESS BURDETT-COUTTS, Holly Lodge Gardens, Highgate, N., July 12, 1892.—"Dear Sirs, Having given your Improved Garden Gully a fair trial, I may say that it proves in use all that you claim for it, and in my opinion has, for the sides of walks and drives, many advantages over the ordinary grating. Perhaps the best proof I can give you of this is that, as opportunity offers, I intend to use them instead of gratings. Faithfully yours, J. WILLARD."—To Messrs. VINCE & VINE.

From W. WALTON, Esq., Secretary to the LONDON CEMETERY COMPANY, The London Cemetery Company, 29, New Bridge Street, Blackfriars, E.C., July 25, 1892.—"To Messrs. Vince & Vine, Highgate. I am very happy to testify that your Patent Garden Gully-Frames in lieu of the old-fashioned gratings answer admirably. They were by my authority fixed in a new pathway made in Highgate Cemetery, and in the recent thunder-showers they were severely tested and were

most effectual in preventing the scouring of the gravel. At the inspection my Directors were much pleased with them, and gave instructions that they were to be used when required at Nunhead Cemetery.—I am, yours truly, W. WALTON, Secretary."

From Messrs. CUTBUSH AND SON, Highgate and Barnet Nurseries.—"Highgate Nurseries, London, July 27, 1892.—Dear Sirs,—Referring to the Improved Garden Gully you fixed for us some months ago, we are glad to say it answers admirably. As you are aware, our Nurseries here are very hilly, and during the recent storms all the ordinary gullies were blocked, whereas yours was in good working order. We shall not hesitate to recommend the same to anyone requiring the gullies for sides of paths and carriage-drives, and we feel certain, when it is known, there will be a great demand.—We are, yours faithfully, WM. CUTBUSH AND SON.—Messrs. VINCE & VINE."

DR. SMILES'S WORKS.

JASMIN: BARBER, POET, PHILANTHROPIST.
Post 8vo. 6s. Fourth Thousand.

"What Jasmin did for himself in poetry Dr. Smiles has now done for him in prose, doing full justice to that part of his life which Jasmin's simple modesty forbade him to record, namely, his unceasing philanthropic efforts. The story is noble as well as touching, and is told by Dr. Smiles with abundance of sympathy and appreciation."—*The Times*.

"Dr. Smiles has performed a praiseworthy task in introducing this little-known but admirable man to English readers. . . . He died worn out at the age of sixty-five. In the south of France he was mourned as the friend of the friendless, as the St. Vincent de Paul of poetry."—*Academy*.

"Dr. Samuel Smiles has given to the world a graceful and sympathetic record of a pure and beautiful human life, teeming with the poetry of action as well as of thought, and redolent throughout of good deeds and loving kindness."—*Daily Telegraph*.

"Il a fait un livre bien personnel et aussi complet que possible. Voilà Jasmin 'raconté' en anglais pour la postérité. C'est M. Smiles qui est le coupable, et son élégant volume nous a tout à fait charmé."—*Revue Littéraire*.

"No one of Dr. Smiles's books is more delightful than this one about the warm-hearted poet of Gascony. Dr. Smiles appears here at his best; for the story of Jasmin's life is full of romance, and the style of this volume has the happy characteristics of ease, simplicity, and beauty."—*Liverpool Mercury*.

"The story of such a life is well worth telling, and it has been admirably and sympathetically told by Dr. Smiles in a book which, to our mind, is one of the most attractive of all his works."—*John Bull*.

"One of the most touching and charming biographies we have ever read."—*Critic* (New York).

JOHN LAING AND SONS, Forest Hill

Nurseries, have pleasure in announcing there is a GRAND OPENING for YOUNG MEN who understand the Nursery Business, in Fruit Vale Irrigation Colony, Rio Puerco Valley, New Mexico, U.S.A. Mr. A. F. SPAWN, the president, sails on November 2, with a number of settlers. Communications should be at once sent to A. F. SPAWN, Esq., 37, Victoria Street, Westminster, S.W.

WANTED, a HEAD WORKING GARDENER, for quiet country place.—Age 40 to 50, unmarried; three under him. Thorough experience in Kitchen and Flower Gardens, Vines, &c.—Apply, by letter, to F. E. FLETCHER, Nergis Hall, Mold, Flintshire.

WANTED, a HEAD WORKING GARDENER, where four are kept. Must be thoroughly competent in all branches. Personal character preferred. Wages, 18s., rising to 20s., cottage and vegetables.—G., Quiville House, Blandford, Dorset.

WANTED, a HEAD WORKING GARDENER, to live in Lodge; one other kept. Must thoroughly understand the cultivation of Stove and Greenhouse Plants, Vines, Melons, Cucumbers, &c., also out-door Gardening. Apply by letter only, stating references and wages required.—G. H., Webb & Sons, The Royal Seed Establishment, Wordsley, Stourbridge.

WANTED, a HEAD WORKING GARDENER (about 40, married), for a Private Gentleman's Fruit Plantation about to be made, 45 miles from London. Thorough experience necessary. Wife for Cook and Laundry, and son or daughter might possibly be employed.—Address replies, with full particulars and experience, and inclusive wages required, besides cottage, to B. H., *Gardeners' Chronicle* Office, 41, Wellington Street, Strand, W.C.

WANTED, a good MAN as SECOND GARDENER, for a private place. Bothy.—Apply, with references, to G. MERRITT, The Nursery, Harpenden.

WANTED, an active young MAN, as UNDER FOREMAN, to assist in the Execution of Orders, and Knifeman.—State age, wages, and references, to WM. TROUGHTON, Nurseryman, Preston, Lancashire.

WANTED, a WORKING OUTDOOR NURSERY FOREMAN.—State where gained experience, age, and wages expected, to NURSERYMAN, *Gardeners' Chronicle* Office, 41, Wellington Street, Strand, W.C.

WANTED, good Indoor PROPAGATOR.—For years under Foreman. Roses, Clematis, and general Soft-wooded Stuff. Wages 20s. to commence.—H. ENGLISH, Clevedon Nursery, Clevedon.

WANTED, a thoroughly experienced PLANT GROWER of Palms, Ferns, Stove and Soft-wooded Plants. Well acquainted with the production of Cut Flowers in large quantities, and capable to undertake the management of men. Apply, by letter, stating experience, references, age, and wages required.—D. S. THOMSON AND SONS, The Nurseries, Wimbledon.

WANTED, a MARRIED COUPLE, as GARDENER and COOK. Gardener must be an industrious and sober man, who thoroughly understands the profession. Good Vegetables and Flowers required. Wife as good plain Cook. In a Gentleman's Establishment; age 35 to 40; trustworthy couple, without children, as they would live and board in the house. Wages, one guinea per week, and all found, except beer and washing. Outdoor man kept to attend to Cows, &c. Unexceptional references required.—Apply at once, by letter, to Mr. STEVENS, 38, King Street, Covent Garden, London, W.C.

WANTED, a respectable YOUTH (17 or 18), quick at Potting, &c., and to write a good hand, to work under Foreman. Must have had experience under Glass. Wages, 15s. per week.—J. MORSE AND SON, Florists and Nurserymen, Dursley.

WANTED, a young MAN, to take Charge of Stool Ground, also Plunging Ground, and Creepers in pots. State wages required.—S. S. MARSHALL, Barnham Nursery, Sussex.

Seed Trade.

WANTED, IMMEDIATELY, an ASSISTANT SHOPMAN, one with knowledge of Cut Flower trade preferred. Apply, with references, stating age and wages required, to JAMES COCKER AND SONS, 130, Union Street, Aberdeen.

WANTED, a JUNIOR CLERK, and as Assistant in Shop, acquainted with Seeds, Bulbs, and Nursery Stock. Apply, by letter, stating experience, reference, age, and wages expected.—D. S. THOMSON AND SONS, The Nurseries, Wimbledon.

WANTED, AT ONCE, a young active MAN, as JUNIOR ASSISTANT in Shop.—Apply, in writing, to N., Nutting & Sons, 106, Southwark Street, S.E.

WANTED, a young MAN, as JUNIOR, in the Office.—Apply, in writing, to S., Nutting & Sons, 106, Southwark Street, S.E.

WANT PLACES.

TO GARDENERS, AND OTHERS SEEKING SITUATIONS.

The Pressure upon our space at this season of the year is so great, we are compelled to state that advertisements received after 6 P.M. on Wednesday will, in all probability, be held over to the next week.

Advertisers are cautioned against having letters addressed to initials at Post-offices, as all Letters so addressed are opened by the authorities and returned to the sender.

Gardeners, Farm-Bailiffs, Foresters, &c.

DICKSONS, Royal Nurseries, Chester, are always in a position to RECOMMEND MEN of the highest respectability, and thoroughly practical at their business. All particulars on application. Telegraphic and Postal Address—"DICKSONS, CHESTER."

SANDERS, St. Albans, can thoroughly RECOMMEND several first-class HEAD GARDENERS.

SCOTCH GARDENERS.—Several superior men of first-class ability seeking re-engagement; also UNDER-GARDENERS.—Particulars from AUSTIN AND McASLAN, 89, Mitchell Street, Glasgow.

RICHARD SMITH AND CO. beg to announce that they are constantly receiving applications from Gardeners seeking situations, and that they will be able to supply any Lady or Gentleman with particulars, &c.—St. John's Nurseries, Worcester.

THOMAS BUTCHER can recommend several HEAD and UNDER GARDENERS of first-rate character and proved ability. Gentlemen seeking such may have particulars free.—Apply to THOMAS BUTCHER, Seed Merchant and Nurseryman, Croydon.

F. SANDER AND CO. can recommend several highly qualified and energetic HEAD and UNDER GARDENERS, of excellent character, and proved ability; men thoroughly fitted for all the various duties of their profession. For all particulars, please apply to—F. SANDER AND CO., St. Albans.

GARDENER (HEAD).—Middle-aged, married, no family. Thoroughly experienced in all branches, Land and Stock if required. Can be highly recommended.—G., 8, Treherne Road, Mortlake, S.W.

GARDENER (HEAD).—Age 47, married; highly recommended as a thoroughly honest, sober, trustworthy, and competent man.—J. BREWER, 12, Eustace Road, Waltham Green, S.W.

GARDENER (HEAD).—Lady HUNT, Appleby Towers, Ryde, can with confidence recommend her Head Gardener, T. D. Myles, to any Nobleman or Gentleman requiring the services of a good Gardener. Has been here ten years, and has had large experience in all matters connected with gardening. Good testimonials from previous employers. Leaving through alterations in the establishment.

GARDENER (HEAD), to any Lady or Gentleman requiring the services of a thoroughly practical all-round man.—Age 43, married, no family; good character.—B. BELL, 19, Peach Street, Queen's Park, W.

HOLLOWAY'S OINTMENT and PILLS.—Chest and Stomach Complaints.—The source and centre of almost every ailment is impurity of the blood; dislodge this poison, and disease departs. Holloway's Pills exercise the inestimable power of thoroughly cleansing each component part of the blood, and rendering this fluid fit to perform its important functions. They cope most successfully with chest disease, stomach complaints, liver disorders, and many other maladies, which were once the besetting dangers of mankind at certain seasons in town and country. The directions for use enable every one to regulate the operation of these Pills with the greatest nicety. Chronic invalids, nervous sufferers, and all whom other treatment has failed to relieve, are respectfully invited to try Holloway's celebrated medicine, which will strengthen and cure them.

AWARDED TWENTY PRIZE MEDALS

AT INTERNATIONAL EXHIBITIONS AT HOME AND ABROAD.

KEITH'S PATENT BOILERS, THE "CHALLENGE," "VIADUCT," "PYTHON," &c.,

FOR HOT-WATER HEATING, "STAND FIRST," require no building work round them, are entirely water-jacketed, and heat from 50 feet up to 20,000 feet of 4-inch pipe respectively. Many thousands are in use all over the world, and the Boilers are unrivalled in power and economy.

KEITH'S "PYTHON" BOILER, as illustrated below, has 1000 square feet of effective heating surface, with 17½ square feet of fire-grate area; heats about 20,000 feet of 4-inch pipe, and is the Most Powerful and Complete Sectional "Special" Hot-water Heating Boiler in the World.

This Engraving "illustrates the most powerful form of Boiler that has yet been made for Hot-water Circulation."—Extract from Hood, on *Warming by Hot-water*, New Edition, 1891.

KEITH'S BOILERS

are almost exclusively used by Her Majesty's Government, at the Home Office, and for the Heating Work of the Prisons throughout the United Kingdom, in preference to all others.

Manufactured under thirty James Keith's Patents in Great Britain, United States, and Canada.

JAMES KEITH (C.E., Assoc. M.Inst.C.E.), Gas, Hydraulic, Heating, Ventilating, and Consulting Engineer. Established 1823. Contractor to Her Majesty's Government. 57, HOLBORN VIADUCT, LONDON, E.C., ALSO AT EDINBURGH AND ARBROATH.

KEITH'S PATENT RAMS & HYDRAULIC RAM-PUMPS, For Raising Water.

The very HIGHEST EFFICIENCY attained in Self-acting Hydraulics, by KEITH'S RAMS.

KEITH'S PATENT "UNIVERSAL" RADIATORS, For Hot-Water Heating. Made in One Piece, and in many Sizes and Modifications. No Joints to Leak. Thousands in use.

Bagshot.

THREE DAYS' UNRESERVED SALE of beautifully-grown and well-rooted NURSERY STOCK, in splendid condition for removal, by order of Messrs. JOHN WATERER & SONS, Limited.

IMPORTANT to NOBLEMEN, GENTLEMEN, and OTHERS.

MESSRS. PROTHEROE AND MORRIS will SELL by AUCTION, on the Premises, the well-known Bagshot Nurseries, Bagshot, Surrey, on TUESDAY, November 8, and TWO FOLLOWING DAYS, at 12 o'Clock each day, several acres of NURSERY STOCK, grown to the greatest perfection, and exceedingly well rooted, comprising a great variety of CONIFERS, splendid specimens for effective planting, 4 to 8 feet; hundreds of well-coloured Golden Retinosporas; very fine specimen Gold and Silver Variegated Hollies, 4 to 6 feet, standard and pyramids; 1000 Green Hollies, 3 to 5 feet; Aucubas, Laurels, English Yews; 2000 named Rhododendrons, 2 to 2½ feet, bushy plants, of the newest kinds; Ponticum Rhododendron in quantity; 1000 Spruce Firs, 2½ to 4 feet, and a quantity of larger plants 4 to 8 feet, specially adapted for Christmas Trees; 2000 Standard Ornamental Trees, 8 to 12 feet; Purple Beech, Limes, Chestnuts, Poplars, &c.; thousands of Flowering Shrubs, in large quantities; small Conifers for potting and boxes, consisting of Cupressus, Retinosporas, &c.

Bagshot Station is on the Nursery, whence goods may be transmitted to all parts.

Purchasers will be allowed until December 31 for removing their lots, and Messrs. WATERER & SONS will undertake to hit and forward any goods bought at the Sale, simply charging for the time and labour occupied.

Stock may be viewed any time prior to the Sale. Catalogues may be had on the Premises, and of the Auctioneers, 67 and 68, Cheapside, London, E.C.

Sale—November 11.

By order of F. SANDER & CO., St. Albans.

NEW ORCHIDS FROM THE NATUNAS ISLANDS.

No other Collector has ever explored this Group.

A remarkable and distinct-looking SACCOLABIUM, provisionally named Sandera, flowers white and amethyst.

An extraordinary large white flowering COELOGYNE, with long racemes; this is no doubt the premier representative of the genus, provisionally named after our intrepid and indefatigable collector, C. Ericsson.

A NEW DENDROBIUM, in the way of D. amethystoglossum. Also a CYPRIPEDIUM, reminding one of the Western Palm-foolium.

Further and full particulars will appear in next week's *Gardeners' Chronicle*.

MESSRS. PROTHEROE AND MORRIS, 67 & 68, Cheapside, London, E.C.

Barnham Nurseries, near Bognor.

BULBS, TO THE TRADE.

JOHN MOOY, BULB GROWER, from Holland,
 begs to inform his Commercial Friends that
 he has arrived in London, as usual, with a choice
 Collection of Bulbs.

WAREHOUSE, 96, DRURY LANE,
 LONDON, W.C.

VICTOR POTATOS
 (SHARPE'S).

This favourite first early Potato, suitable for any Garden,
 indispensable for Forcing and Early Borders, and likely to take
 the first rank amongst first earlies for market use. Quality
 and yield all that could be desired. One well known market
 grower has this year had a yield of 15 tons per acre on a large
 acreage. London and Manchester salesmen speak highly of
 their quality, and report that Victors will keep their bloom
 and have a fresh appearance after being in the market some
 days, when other early Potatos have become discoloured and
 unsaleable.

The stock we offer is the true yellow-fleshed variety and not
 the white variety, which is often substituted.
 Price per cwt. and ton. State requirements to

W. W. JOHNSON & SON,
 Seed Growers and Merchants, Boston, Lincolnshire.

TRADE OFFER.—FIGUS ELASTICA, &c.

THE "EARLY RIVERS" NECTARINE.

A Seedling Nectarine raised by Mr. T. Francis Rivers, the earliest Nectarine existing, ripening twenty-one days before Lord Napier, measuring 9½ inches in circumference, weight 8 ounces, freestone, brilliant in colour, flowers large.

This Nectarine is offered on the following terms, viz.: by Subscription, at £2 2s. each, provided that a sufficient number of Subscribers is received.

Strong young plants, in pots, will be delivered in March or April, 1893.

A First-class Certificate was awarded this Nectarine by the Fruit Committee of the Royal Horticultural Society, in July, 1892.

For Opinions of the Press, apply for Circular, post-free.

NEW SEEDLING PEAR, "CONFERENCE," RIVERS.

Certificated by the Royal Horticultural Society.

Fruit large, pyriform; skin dark green and russet; flesh salmon coloured, melting, juicy, and rich. Tree robust and hardy, making a strong healthy growth on the Pear and Quince stocks. Very prolific, a good garden and orchard fruit, and a valuable market sort. It ripens from the first to the third week in November.

Strong trees, 3s. 6d. each.

ODONTOGLOSSUM CRISPUM ALEXANDRÆ.

BEST VARIETY.

GUILLERMO KALBREYER begs to offer the above well-known and justly-prized Orchid at the following prices, free on board of Royal Mail Company's steamers, at Savanilla:—£40 per 1000 good and healthy pieces.

G. K. also can supply:—

ODONTOGLOSSUM LUTEO-PURPUREUM,
" CUSPIDATUM PLATIGLOSSUM,
£36 per 1000.

CATTLEYA TRIANÆ, best variety, £8 per case.

Each case contains from fifty to sixty good, strong pieces, and measures about 20 inches by 34 inches.

The plants are packed with the greatest care and best method, but under no circumstances will G. K. hold himself responsible for the state of plants on their arrival in Europe. Conditions:—All Consignments are shipped entirely at Buyer's risk and expense from port of shipment. Plants ordered must be paid for on receipt of bill of lading to Messrs. ROESING BROTHERS AND CO., 10, Basinghall Street, London, E.C., who will then give orders for forwarding the consignment to the Purchaser.

The best time for dispatching Orchids from here, and to establish them with the best advantage in Europe, are the months—December to April.

Address:—**G. KALBREYER, La Flora, Bogota, Republica de Colombia.**

Cablegram Address:—**FLORA, BOGOTA.**

ROSES IN POTS

HIGHEST AWARDS, in 1892, at the International Horticultural Exhibition (Two Gold Medals); Temple Show of the Royal Horticultural Society (Silver Cup); and Royal Botanic Society (Silver-Gilt Medal).

WM. PAUL & SON

Respectfully solicit Orders for Pot Roses, their Stock being this year the *largest* and *finest* they have ever had, and unsurpassed, if equalled in quality, by any in the Trade.

Extra-sized plants of **TEA** and **NOISETTE** VARIETIES, in 8-inch pots (including Climbing kinds for Conservatories, &c., with 8 to 10-foot shoots), 42s. to 60s. per dozen.

Extra-sized **HYBRID PERPETUALS**, in 8-inch pots, 24s. to 36s. per dozen.

Smaller Plants, in 5 and 6-inch pots, 14s. to 30s. per dozen.

Half-Specimens and Specimens, the finest collection in existence, 5s. to 63s. each.

Immense Stocks of Standard, Half-Standard, Dwarf, and Climbing Roses, in the Open Ground, ready for removal from end of October onwards.

Also large collections of Fruit Trees, Hardy Trees and Shrubs, Camellias, Bulbs, &c.

SALE, NOVEMBER II.

BY ORDER OF F. SANDER AND CO.,
ST. ALBANS.

NEW ORCHIDS,

FROM THE

NATUNAS ISLANDS.

No other Collector has ever explored this group.

A remarkable and distinct-looking **SACCOLABIUM**, provisionally named SANDER.E; flowers white and amethyst.

An extraordinary large white-flowering **CŒLOGYNE**, with long racemes; this is, no doubt, the premier representative of the genus. Provisionally named after our intrepid and indefatigable Collector, C. ERICSSON.

A new **DENDROBIUM**, in the way of D. AMETHYSTOGLOSSUM.

Also a **CYPRIPEDIUM**, reminding one of the Western PALMIFOLIUM.

Further and full particulars will appear in next week's "Gardeners' Chronicle."

PROTHEROE & MORRIS,

THE

Gardeners' Chronicle.

SATURDAY, OCTOBER 29, 1892.

DR. ROBERT LYALL

(BOTANIST AND TRAVELLER, 178(?)—1831).

ROBERT LYALL was born in Scotland some twenty years before the close of the last century, and the story of his wanderings and botanical observations and collections is apparently so little known that a brief notice of his life may be worth recording in the pages of the *Gardeners' Chronicle*. Mr. Dowie, the courteous assistant-clerk of the University of Edinburgh, who has searched the records in his charge, states that Robert Lyall's name first occurs in the index of the University album as attending the class of chemistry in 1801, and that from 1807—1810 the name of the same student appears as studying in various other classes at Edinburgh; but he does not appear to have taken a degree in medicine. As, however, according to his own account, he states that he was at one time studying at Manchester, some of our Manchester correspondents may be able to afford information on this point. Although apparently unsuccessful in the practice of his profession, Dr. Robert Lyall published in *Nicholson's Journal* (vols. xxiv.—xxviii.), between 1809—1811, some papers on the "Irritability of Plants" (a list of which appears in the Royal Society's Catalogue of Scientific Papers), which attracted some attention among the scientists of the day. Domestic or pecuniary troubles seem to have driven him away from Great Britain shortly afterwards, for, to use his own words, he "twice found an asylum from misfortune, and passed some of the best years of his life," in the Russian empire. Dr. Lyall has left no record of the exact date of his first visiting Russia, but from interval evidence of his published works, it appears that in 1815 he resided at St. Petersburg as physician to a nobleman's family, and travelled to Kaluga with Mr. Pollaratskii. He is next found attached for four years (1816—1820 presumably), to the establishment of the Countess Orlof-Tschémska, at Ostrof, about 16 miles from Moscow, in the summer months, and in winter at the ancient capital, which was then being rebuilt on a grand scale after the Napoleonic invasion four years previously.

Whilst in the neighbourhood of Moscow, Dr. Lyall accompanied Dr. Goldbach, Professor of Botany, in examining the plants in and near the city, and prepared a catalogue of them. "Several years previously," writes Dr. Lyall, "when studying the Mushrooms with unremitting zeal at Manchester, I had the curiosity

* Dr. Lyall was a corresponding member of the Literary and Philo-sophical Society, and of the Natural History Society of Manchester. It is to be hoped that this Society has preserved a notice of Dr. Lyall's labours and correspondence. Can your Manchester correspondents give information on this point? Mr. Charles Bailey informs me there is no record in this Society's papers of Lyall. S. P. O.

to enumerate the species which are indigenous in Britain, according to Withering's *Arrangement of British Plants*, and found their number, if I do not deceive myself, to be above 500. I now am ready to exclaim—how many of these species are edible!—how many would the Russians, by their modes of preparing and dressing, render edible! What a supply of food, especially for the poor, in hard times, may be annually lost for want of knowledge! Lyall published his *Remarks on Mushrooms*, "with catalogues of the species reckoned edible by the Russians and notices of the method of preparing them." Subsequently, when in London, he had a conversation with his distinguished friend, Sir Alexander Crichton, who informed him that the Misses Crichton, accompanied by a servant who followed his family from Russia to England, had repeatedly collected and used numerous species of Mushrooms reckoned edible in Russia, but thought poisonous in Britain. So strongly was the cook of the latter opinion, that she would not allow the said poisonous Mushrooms to be prepared in her dishes; she would not even consent to touch them, far less to prepare them, lest death should be laid at her door. They were consumed, however, with avidity, and produced no bad effect. In fact, Dr. Lyall was among the first, if not one of the very first, in this country, who was persuaded that the history of edible Mushrooms, and the modes of dressing them, had not attracted sufficient attention from writers in any of the languages of Europe. He was convinced of the importance of the investigation of this subject, even in a political point of view; for only in times of famine, such as that which has prevailed over vast districts in Russia quite recently, can the value of the edible Mushrooms be rightly appreciated.

"The knowledge of edible Mushrooms," says Dr. Lyall, "like a tradition, has been handed down in Russia, from parent to child, through a long series of ages; and the discrimination of these from the hurtful or poisonous Mushrooms is learned by practice in the years of infancy and youth. Such a valuable acquisition to the store of general knowledge can only be made by the foreigner who is a botanist, and through him alone may be expected to be communicated to foreign nations, which, in the course of time, may share in the rich supply of dainties for nourishment, as well as for the gratification of taste—a supply which hitherto has only been allotted for the use of the more northern nations. The liberal consumption of Mushrooms by the natives of milder climes is more securely prevented by fear than if they were contraband articles, or imported under a heavy tax."

In 1821, Dr. Lyall was attending General Natschokin at Semeonovskoyé, also in the vicinity of Moscow; but he seems to have been glad to terminate his engagement with this officer, and he next travelled, in the double capacity of conductor of the journey and physician, with the Marquis Pucci, Count Salazar, and Mr. Edward Penrhyn through the Crimea, Georgia, and the other southern provinces of Russia. Starting from Moscow in April, 1822, he returned from his journey in August, and then proceeded to St. Petersburg.

Dr. Lyall's description of the Botanic Garden of Górenki, 17 miles from Moscow, which belonged to Count A. K. Rasumóvskii, as they existed in 1822, may be quoted as interesting to readers of the *Gardeners' Chronicle*.

"Its situation is rather flat, in consequence of which the triumphs of labour and art are so much more conspicuous. The mansion is quite a princely residence. It is large, not overladen with ornaments, and built in a good style of architecture. The interior apartments are very spacious and elegant, and the furniture is quite consonant with the exterior impression. In the basement story is a fine promenade through a gallery 910 feet long, including at each end a commodious forcing-house. It has a magnificent appearance, and is made doubly agreeable by the sweets of Orange and Lemon groves, as well as by the quantities of Peaches and Apricots produced. The gardens are laid out with a good deal of taste.

Gravel walks, ponds, lakes with islands, together with temples and statues, are their chief ornaments, and in them grow nearly 2000 perennials. The collection of plants here amounts in all to between 9000 and 10,000. The hot-houses are eleven in number, in six separate buildings, arranged in two rows. Some of them are extremely large, and the front of the whole, collectively, amounts to 1148 feet. Here are enjoyed Asiatic pleasures in the rigorous climate of Russia—walks amidst groves and woods of tropical vegetation, even when the cold is 35° below zero of Fahrenheit. The establishment at Górenki, *in toto*, is one of the most magnificent in the world, and perhaps its equal was never supported by any individual. The cost for wood alone in the cold climate of the north, is enormous, and I have been assured that the annual expenditure has been from 70,000 to 100,000 roubles. Górenki has been known about twenty-two years by its botanical gardens, but it is chiefly within the last eighteen that it has acquired such renown. Dr. Radóvskii, a man of talents, was its director for a few years, and had formed a considerable collection of plants. My worthy friend, Dr. F. Fischer, that distinguished botanist, and most amiable man, has been director of these gardens for about sixteen years, and to him almost the whole celebrity of Górenki is due. His zeal and discoveries are well-known throughout Europe, and require no encomium from my pen. . . . The gardens of Górenki form a famous nursery, and may be called the Botanical Emporium of the Russian empire; of the Ukraine, the Crimea, the Caucasus, Georgia, part of Tartary, Siberia, Kamtschatka, and the Russian isles, between the latter and America. Catalogues of the plants contained in this nursery are frequently published, and are distributed throughout Europe. By connections already established in different countries, seeds have been received at Górenki of numerous undescribed plants. Indeed, many new plants which have enriched and embellished the botanic gardens of Europe, most probably would have remained unknown to the botanic world for many years to come, but for Górenki and its director. The correspondence of Dr. Fischer with Europe, and the number of packets of seeds annually sent by him to the botanic gardens, and to distinguished patrons of botany is so enormous, that I dare not state it, fearful of exciting suspicions as to its authenticity. For these he receives seeds from all quarters in exchange; a practice which he wishes to encourage to the greatest extent."

Unfortunately these gardens have come to ruin in consequence of the immense debts of the Count. The collection was offered to the Russian Government for 300,000 roubles, but as the Crown would only give 150,000 roubles, the offer was rejected. Dr. Fischer became the director of the extensive botanic garden at St. Petersburg, and the gardens at Górenki are gone. Perhaps some of the correspondents of the *Gardeners' Chronicle* who may happen to know the vicinity of Moscow can give information as to whether any attempt has been made to reinstate this once-famous establishment.

Dr. Lyall made no secret of his opinions, nor of the contents of his MS. works, while in Russia; but, at length, he got timely notice that his papers might be seized, in consequence of a report having arisen that he was about to quit Russia on account of the severe observations contained in his volume, which was said to be already published in London. By an excellent opportunity he despatched what he esteemed his dangerous papers; and, afraid of a visit from the police, he made all haste with his family to Britain, arriving in London sometime in August, 1823. The same autumn his publishers (Cadell in London, and Blackwood in Edinburgh), brought out Dr. Lyall's well-known book on Russia, *The Character of the Russians, and a Detailed History of Moscow*, a portly quarto volume, fully illustrated, which was dedicated to the Emperor Alexander. The Russian Emperor, however, was displeased at the frank manner in which the manners, mode of life, and morals of his nobles were exposed to the public in the pages of this volume, which, nevertheless, long remained a standard work on the subject. This book was followed by *Travels in Russia, the Crimea, the Caucasus and Georgia*, in two vols., 8vo, brought out by the same publishers in 1825. Meantime, the author had published *An Account of the Organization, Administration, and Present State of the Military Colonies in Russia in 1824*; in this volume he included an interesting journal of General Yermolof's embassy to Persia in 1817.

The disapprobation expressed by the Czar of all the Russias prevented the return of Dr. Lyall and his family to that country. That his conduct was approved by his superior officers, Sir Alexander Crichton and Sir Jas. Wylie, seems evident from the fact that after a short residence in England, he was appointed to an important foreign mission by the government of which the Earl of Liverpool was

Prime Minister, and Lord Castlereagh the Foreign Secretary.

On the death of Mr. Hastie (the British Agent at the capital of Madagascar, October 8, 1826) becoming known in England, Dr. Lyall was appointed to succeed him, and proceeded immediately with his wife and family to Mauritius, where he arrived in the summer of 1827. Hearing that King Radama was expected to visit the coast, he proceeded to Tamatave, where he was introduced to the King, by whom he was received with all the respect to which his office entitled him; but as the time was unfavourable for entering the country or proceeding into the interior, he returned to Mauritius, and remained there till the return of the season suitable for journeying up to the country of the Ilovas, the following July, 1828. On his journey up to Antananarivo, he received tidings of the illness of Radama, and hastened with all possible despatch to the capital, but he did not arrive until August 1, when the King's death had actually taken place, although the fact had not been announced to the people. When he arrived, he was received with the usual salute of cannon and other marks of attention from the Malagasy Government, but had no opportunity of presenting his credentials or holding any official intercourse with the Ministers. All public business was suspended by the national mourning, and in these circumstances Dr. Lyall and his family remained at the capital as private individuals until November 28, when an official message was brought to him by the officers of the palace, to the effect that the new Sovereign, Queen Ranavalona I., did not feel herself bound by the treaty of her predecessor, the great Radama, and that she would not receive him as the agent of the British Government; and four days afterwards he was informed that the Queen would no longer receive the subsidy which the British Government granted to Radama, although she did not intend to revive the slave trade in her dominion. Mr. Lyall continued to reside at the capital until March, 1829, when he requested permission to proceed to Tamatave. A fortnight afterwards, on March 29, his family were astonished to see a large crowd of natives coming to their house early in the morning, headed by the keepers of the idol Ramahavaly, who carried that effigy on a long pole. One of Dr. Lyall's servants was seized and put in irons, and the agent and his sons were peremptorily ordered to leave the house and proceed to Ambohipeno, a village some six miles outside the city. He was not even allowed time to change his clothes, to take any luggage, or even re-enter his house to take leave of his family. The courtyard of his house was filled with snakes, large bagsful of which had been brought and emptied out on the ground. These reptiles were supposed to be the servants of the god Ramahavaly and the instruments of his wrath. Dr. Lyall was told that the idol ordered him to leave, and the idol-keepers hurried him away on foot, refusing even to allow him to ride in his palanquin. The idol and its escort, each of whom carried a snake held by some dried grass, followed him, accompanied by a large body of spectators who had been attracted by the tumult. Mr. Freeman, one of the missionaries, came to the assistance of Mrs. Lyall and the rest of her family, and obtained permission to obtain bearers to carry them and their effects to join Dr. Lyall at Ambohipeno, from whence they were all allowed to proceed to the coast on April 22.

The reason assigned for this outrage upon the person of the British Agent, was that he had proceeded himself, and had allowed his horse to approach one of the villages sacred to the idol, and that he had further transgressed by sending his servant to catch butterflies, reptiles, and botanical specimens which he was collecting for scientific purposes.

Dr. Lyall managed to secure a certain proportion of his botanical specimens which he transmitted to Kew, in the herbarium of which establishment many of his collections still remain. Unfortunately Dr. Lyall contracted fever during his journey down to Tamatave, and although he survived long enough to live a year or more in Mauritius, he ultimately succumbed to that malady at Port Louis in 1831.

His correspondence whilst in Madagascar and Mauritius has fortunately remained, and duplicate volumes of it are to be found in the Record Office among the documents of the Colonial Office.

[Extract from Britten & Boulger's Biographical Index of British and Irish Botanists, published in *Journal of Botany*, No. 322, October, 1889, vol. xxvii., p. 311.] "There is a genus of acrocarpous mosses created by Robert Brown and called 'Lyella,' but whether this is after the botanist named above I am not aware."—*Captain S. Pasfield Oliver, late Royal Artillery, Moray House, Stokes Bay, Gosport, August 1, 1892.*

NEW OR NOTEWORTHY PLANTS.

PLEUROTHALLIS TERETIFOLIA, *Rolfe, n. sp.**

This most remarkable little *Pleurothallis* is a native of Pernambuco, in Brazil, and was introduced by Messrs. Charlesworth, Shuttleworth, & Co., of Heaton, Bradford, together with *Cattleya labiata*. It belongs to Lindley's group *Brachystachya*, and for the present may be placed next to *P. teres*, Lindl.

is also very remarkable, and much thinner in texture than the rest of the flower. Altogether, it is a very interesting little plant. *R. A. Rolfe.*

CHRYSANTHEMUM-BOX AND STAND.

WHATEVER may be the outcome of the Conference held recently under the auspices of the National Chrysanthemum Society with regard to increasing the size of stands, it is a fact that the bulk of the blooms exhibited at the present time need more space to show them off properly than is afforded by the present show-stands, and which are regarded as of regulation size. For some years now, some few of the leading Chrysanthemum societies have recognised this want, and have inserted a clause in their schedules to the effect that the stands for Japanese blooms may be larger than those previously employed and allowed. If all societies were to adopt this view, not making it compulsory that all stands must be larger for Japanese, the end, it appears to me, would be gained, because those persons now so adverse to all change would be quick to note the advantages

suffice for all sections, except the Japanese, and for the reflexed and incurved blooms in the Japanese, where these are required to be shown as a distinct class. At the largest exhibitions it seems quite necessary now to have classes for both these, where space and funds will allow of the addition. For the Japanese varieties the board should be 28 inches long by 21 inches wide, 8 inches in depth at the back, 3 inches in front; this is a substantial increase, and one that will last for some years, and avert complaints as to want of size now heard. The regulation pattern at present is 2 feet long and 1½ feet wide, 6 inches high at the back, and 3 inches at the front. This size suffices for twelve blooms.

For twenty-four blooms, two stands of twelve each are usually employed, as being more convenient than one of 4 feet. The question of transit-costs will crop up with the advent of larger stands, and that of expense in making them will be another item to be considered by those who require additional space. Instead of going to the cost of providing what are known as travelling boxes made to fit the stands, with the blooms already arranged on them, I would suggest a rough box fitted with loose trays, one fitting on

FIG. 79.—A STAND OF JAPANESE CHRYSANTHEMUMS. (SEE PAGE 522)

It is remarkable for its narrow terete leaves, somewhat like those of a *Brassavola*, but in other respects the habit is that of *Pleurothallis*. The racemes are pendulous, three to seven-flowered, and the flowers themselves are horizontal or sub-erect, of a dull brownish claret colour, puberulous outside, and the sepals are so connivent, that the flowers only open at the summit. The lip, described in detail below,

* *Pleurothallis teretifolia, n. sp.*—Plant densely tufted, about 9 inches high. Stems slender, about 3 to 5 inches long, sometimes shorter, with three membranous sheaths. Leaf terete, obtuse, slightly channelled at base, 2 to 2½ inches long, 1½ to 2 lines broad. Raceme slender, pendulous, 1 to 2½ inches long, three to seven-flowered. Bracts sheathing, obtuse, 1 to 1½ line long. Flowers 6 to 8 lines long, and of a dull brownish claret colour. Sepals fleshy, connivent, linear, subobtuse, minutely-puberulous, the lateral ones slightly falcate. Petals, obovate, oblong, obtuse, 2 lines long, rather brighter than the sepals. Lip light yellow, 3 lines long, with a long slender unguis nearly equalling the limb, and with a pair of sagittate teeth at its base. Limb oblong, subobtuse, minutely ciliate, base cordate. Column two-thirds as long as the petals, apex tridentate, pollen masses two. Native of Brazil.

gained by the bigger stands for displaying the blooms, and soon would follow suit, especially when they saw their chances of winning prizes narrowed, owing to their failing to grasp the good points of these stands. If exhibitors of larger blooms intend to win prizes they must adapt themselves to circumstances, and move with the times. To fail to win looks in this case like "sinking the ship for a ha'porth of tar." There is one point, though, about this increased size of stand, which those who are inexperienced should pay attention to—not to have the increase too great, or the remedy may be worse than the evil. Blooms placed on a stand that is too large for them do not look so well as those which are too large for a stand, for the reason that the size of the stand lessens in appearance the size of the blooms.

During a somewhat wide experience of Chrysanthemum showing last season, I came across several instances of too much board and too little flower, which is a mistake in point of appearance, and entails unnecessary expense. The existing size will

the top of another, these being lifted out at the top by means of holes cut in the trays, one at each end. Such a box can be made of any size that strikes the owner, because I suggest that the stands upon which the blooms are to be arranged should be carried loose to the show, the blooms being placed on them there. The box would then simply act as a receptacle for carrying the blooms, and nothing more. Even with the present method of carrying the blooms, they are seldom exhibited as arranged on the stands before leaving home; and it would be just as easy to lift the blooms out of the trays singly at the show, and put them in their places on the stand—in fact it would be simpler than the present methods. The box could be made in packing-case form, only that it need not be extra stout, and should be fitted with a hinged lid for convenience and security; blocks of wood could be fastened to the sides of the box for the trays to rest upon, a screw fixed on the top of the tray would prevent the trays moving should the box chance to be turned upside down. Holes the

same size as the cup which contains the water could be bored in the tray in which the flowers would be placed during transit. To obviate the difficulty which now exists of the cups of the tray above coming in contact with the blooms beneath, as in the case of the stands in ordinary travelling cases, the holes could be cut angle-wise; in the trays the blooms could be packed more easily and securely.

The blooms which are intended for the front row in the stand, being smaller, will need to be packed in the lower tray, the largest, for the back row, on the top, so that in removing them simplicity in the arrangement on the stands is effected. Less space between the trays in the lower part of the box would be required, owing to the smaller size of the blooms in the lower stands. Such a travelling case could be made by any one at a small cost, and if regard were paid to the lightness of the wood used, the cost of transit and of labour in removal would not exceed what is the rule now. *E. Molyneux.*

[As an illustration of the manner in which they can grow Chrysanthemums in Tasmania we give a figure (see p. 521) from a photograph sent us by Messrs. F. Walker & Co. of Launceston. It not only shows how well our friends at the Antipodes can grow their flowers, but it also illustrates a point raised by Mr. Molyneux and shows how unadvisable it is to exhibit flowers of different sizes and sections on the same board. It is useless, we suppose, to repeat our oft-expressed opinion that our colonial friends would render much greater services to horticulture by developing their native flowers than by slavishly imitating European customs. The Tasmanian flowers are singularly beautiful. Ed.]

THE WHEAT CROP OF 1892.

THE autumn of 1891 was generally unfavourable for wheat sowing. October, which is the great seed-time, was exceedingly wet. At Rothamsted, nearly 7 inches of rain were measured during the month; and there was also a considerable excess in the eastern, midland, and southern districts of England—especially in the southern. There was, again, a considerable excess of rain in December. Not only, therefore, was the land generally in too wet a condition for favourable sowing and early growth, but there would be in many cases unusual loss of soluble manurial matters, especially of nitrates, by drainage. From the beginning of January to nearly the end of May the rainfall was considerably below the average, almost throughout the Wheat-growing districts of England and of Scotland. It was also below the average in the eastern, midland, and southern districts of England, until past the middle of June. From this time to the end of August there was, upon the whole, a considerable excess of rain, which was pretty continuous during the greater part of July and the latter half of August.

As to temperature, the autumn of 1891—indeed, the whole period September to December inclusive—was considerably warmer than the average, excepting at the end of November, and again towards the end of December, the week ending December 26 being extremely cold. The greater part of January was also very cold; but warm weather set in towards the end of the month, and continued to about the middle of February. From this time, however, until the end of the first week in May, the temperature was, with the exception of a short period early in April, considerably below the average throughout the chief Wheat-growing districts of the country. The remainder of May and the beginning of June were warmer than the average, the end of May being unusually hot. Excepting early in July, when the temperature was rather over average, the period from the second week in June to nearly the middle of August was, upon the whole, considerably colder than the average.

The season may, therefore, be summed up as one of very great fluctuations, both of rainfall and of temperature. Up to the middle of June, however, there was a prospect of a fair crop of Wheat in many localities, and this was particularly the case at Rothamsted; but the frosts which occurred about and after the middle of the month, following some weeks of high temperature, did immense damage. The result was blight

and mildew over large areas, and in this way the crops in the experimental field suffered very much. Lastly, the harvest weather has very generally been unfavourable.

The following table shows, in the usual form, the produce of Wheat on the selected plots in the field at Rothamsted, which has now grown the crop for forty-nine years in succession. It also gives, for comparison, the average produce over the immediately preceding ten years, the previous thirty years, and over the forty years, 1852 to 1891, inclusive.

* 25½ bush. = 25½ bush. at 61 lb., and 25½ bush. at 60 lb. p. bush.
 † 19½ bush. = 29½ bush. at 61 lb., and 29½ bush. at 60 lb. p. bush.
 ‡ 27½ bush. = 26½ bush. at 61 lb., and 26½ bush. at 60 lb. p. bush.
 § 27½ bush. = 27 bush. at 61 lb., and 27½ bush. at 60 lb. p. bush.

Before proceeding to draw any comparison between the produce of the present year and that of past seasons, it will be well to call attention to the fact that, over the last ten years, the average produce of the unmanured plot was rather less than that of the preceding thirty years; but, that of each of the manured plots was considerably higher over the last ten, than over the preceding thirty years. Thus, the produce by farmyard manure, was nearly 5 bushels higher over the last ten, than over the preceding thirty years, and the mean of the three artificially-manured plots was 2½ bushels more over the ten, than over the thirty years. Again: the general average produce of the selected plots, as shown in the last column, was 2½ bushels more over the last ten than over the preceding thirty years; or, if the forty years be divided into five periods of eight years each, the last eight years ending 1891, give a higher average produce than either of the four preceding eight yearly periods, and much higher than the two immediately preceding periods 1876-1883, and 1868-1875. In other words, the average produce of the last eight or ten years is considerably higher than that of the preceding years of the forty, and this should be borne in mind in comparing the produce of the present season with past averages.

It will be seen that, in 1892, the unmanured plot yields only 9½ bushels per acre, against an average of 12½ bushels over the last ten years, and of 13½ bushels over the preceding thirty years, showing a deficiency, therefore, of about 3½ bushels compared with the average produce of preceding years. The farmyard manure plot yields this year only 33½ bushels, against an average of 38½ over the last ten years, equal to a deficiency of nearly 5 bushels, though the produce is very nearly the same in the

present year as the average of the thirty years preceding the last ten. Two out of the three artificially-manured plots also yield much less than the average of the last ten years, but the third shows scarcely any deficiency. Taking the mean of the three artificially-manured plots, there is a deficiency of more than 3 bushels compared with the average of the last ten years, and of nearly a bushel compared with the average of the preceding thirty years. Upon the whole, however, the artificially-manured crops do not show so great a deficiency as the farmyard manured, or the unmanured. This is doubtless partly due to the fact that the greater portion of the artificial nitrogenous manure is not applied until the spring, and so it has escaped the autumn and winter rains, and loss by drainage. In contrast to the above results obtained this year, it may be observed that in 1891 the produce of the farmyard manure plot was 48½ bushels, which was 11½ bushels more than the average of the preceding ten years by that manure, and 7½ bushels higher than the mean produce of the artificially-manured plots in the same year. This year, on the other hand, the produce by farmyard manure is even slightly less than the mean of the three artificially-manured plots. It is probable that spring-sown and spring-manured Wheat, when got in in good time, will generally be better than the autumn-sown and autumn-manured, by reason of the less loss of nitrates by drainage.

Taking as usual the mean produce of the unmanured, of the farmyard manured, and of the three artificially-manured plots taken as one, the average produce of the selected plots is seen to be 25½ bushels; and as the crop was harvested under favourable conditions as to weather, the weight per bushel was 60½ lb., which is equal to the average of the last ten years, and more than the average of the preceding thirty years. The table further shows, that the produce of straw on the selected plots was this year considerably below the average; and it was besides much damaged. There is too much reason to believe that the result has been much the same in the country generally, and so far as this is the case, the farmer will not, as sometimes happens, have some compensation for a poor yield of grain in an abundance of straw.

As shown in the notes at the foot of the table, the 25½ bushels at the actual weight per bushel, correspond to 25½ bushels at 61 lb., and to 25½ bushels, or rather less than 26 bushel, at the standard weight of 60 lb. per bushel, which is now adopted by the Departments in the Official Returns. There can be no doubt that large areas of the crop of the country have been got in later and in worse condition than that of the experimental plots at Rothamsted. Indeed, the reports show more and more damage the later the harvest. Under these circumstances, it is pretty certain that the yield of the country at large will be less than that indicated by the mean results on the selected plots. But when it is considered that every bushel per acre more or less on our present reduced acreage, would only correspond to little more than a quarter of a million (286,898) quarters, it is obvious that so far as any estimate of the requirement for consumption, and consequently of the required imports, is concerned, exactitude in the estimate of the home crop comes to be of less importance than formerly; and this is especially the case in a year of low yield per acre as well as reduced area.

If, however, we adopt, by way of illustration, the yield indicated by the results on the experimental plots, namely 25½ bushels per acre at 60 lb. per bushel, as the average yield on the 2,295,183 acres under the crop in the United Kingdom, the aggregate home produce would be less than 7½ million (7,423,483) quarters; and deducting from this 2 bushels per acre for seed = 573,796 quarters, the home produce available for consumption would be less than 7 million (6,849,687) quarters. Next, taking the estimated population of the United Kingdom at the middle of the current harvest-year at nearly 38½ millions (38,318,588), and the consumption per head at 6 bushels of 60 lb. per bushel, as adopted last year for reasons then fully explained,

the total requirement for consumption would be 28½ million quarters (28,738,941). Deducting from this the amount assumed to be available from the home crop, there would remain nearly 22 million quarters (21,889,254) required to be provided from stocks and imports. We have thus the remarkable result that, even on the too favourable assumption of rather less than 26 bushels per acre, the produce of the reduced area under the crop in the United Kingdom would, after deducting the amount required for seed, supply considerably less than one-fourth of the total requirement for consumption! Or if, on the other hand, we were to suppose the crop of the country at large to amount to only 22 bushels per acre, the quantity of it available for consumption would represent only one-fifth of the total requirement. As already said, on the higher estimate of the home produce, the quantity required to be provided from stocks and imports would amount to nearly 22 million quarters, and on the lower estimate it would amount to almost exactly 23 million quarters, or only a little over one million more.

It may be observed that our estimate of the average yield of the country at large last year was thirty bushels per acre, at 60 lb. per bushel, and the evidence at command is in favour of the assumption that the estimate was more probably too low than too high. According to it, the quantity required to be provided from stocks and imports to meet the consumption of the harvest year was about 20 million quarters at 60 lb. per bushel, but the actual net imports within the period amounted to nearly 23 million quarters at 60 lb. per bushel. It is admitted that at the end of the past harvest-year the stocks of foreign Wheat in hand were very unusually large, whilst those of the home crop of 1891 were also large. With such an excess of supply over the requirements for consumption, there can be little surprise at the very low prices prevailing; nor can there be much doubt that whether the requirement for the current harvest-year be 22 or 23 million quarters beyond that supplied by the home crop, the accumulated stocks and further imports will prove adequate for our wants. *J. B. Lawes, Rothamsted, Oct. 20, 1892.*

FRUIT TREES ON NORTH WALLS.

THE advice of your correspondent, "H. W. W.," is worthy of consideration, viz., "never to put all your eggs in one basket," and in compliance with this maxim, do not plant all your fruit trees of whatever species upon the same aspect. He mentions the circumstance of having during the current season obtained a crop of Coe's Golden Drop Plum from trees trained to the north side of a wall, or on a north aspect, so that no doubt the bloom was somewhat later in expanding than that of similar trees trained on a south or on an east aspect, which were all destroyed by the late spring frost. I can well confirm the fact of this fine Plum, although now a very old variety, still one of the best, annually ripening its fruit upon an aspect facing due north. This Plum appears to have originated in the town of Bury St. Edmunds more than a century ago, and in a large garden near to that town there are, or at least there were, two large trees of this variety, which occupied a considerable portion of the north side of a somewhat high garden wall. These trees could only, at most, have a very few hours of direct sunshine, and that in the very early morning and late in the evenings, so that, as might have been expected, the blooms were somewhat later in expanding; but they had at the same time the advantage of escaping the effects of late spring frosts, which not infrequently proved fatal to that of trees upon a south, west, or east aspect, while the summers generally proved long enough to enable the trees on the northern aspect to ripen their fruit, which was in all respects as fine and as well flavoured as that of the trees on other aspects. It is quite possible that the northern sides of garden walls might with advantage be used more frequently than is at present the case,

for the purpose of training other species of fruit trees than the Morello Cherry and the red Currant upon, particularly in cases where, on account of danger from late or spring frost, it is desirable to retard rather than to hasten the expansion of flower buds.

As the season advances, the effect of sunshine upon the south side of a wall influences, to a very considerable extent, the opposite or northern side, so that there is possibly less danger to be apprehended from unripe fruit or immature wood and fruit-buds for the succeeding season than might be supposed. The bearing shoots and fruit-buds of the Morello Cherry, when trained, as is usually the case, on a northern aspect, seldom fail to ripen, and the same might be found to be the case as regards other varieties of the Cherry. Most varieties of the Plum, and many varieties of the Pear, will be found to succeed on a north aspect, and even the Apricot might, to some extent, be tried on this aspect. From its well-known habit of blooming so early in the season, its blooms, or embryo fruit, is possibly more frequently injured or even entirely destroyed by late frost than is the case with any other hardy fruit, and if its period of blooming could to some extent be retarded, it would doubtless be found to be an advantage. Most, if not all, the best varieties of Gooseberries will succeed upon a north wall, and the fruit will ripen as early, and will be found to be of as good quality as that of the same sorts produced on bushes fully exposed to the influence of the sun. It is not here intended to recommend the selection of a northern aspect for the cultivation of the Apricot, nor yet of the Plum, nor the Pear, further than to a limited extent, or by placing a portion of such trees on various aspects, an entire loss of any particular crop of fruit is less likely to occur. *P. G.*

THE HERBACEOUS BORDER.

THE PENTSTEMON.

Frost and wet combined made sad havoc of the garden flowers in October. The Michaelmas Daisies, of course, are less affected by the weather than any other hardy flower, but next to them come the Pentstemons. We flowered this summer a number of species of Pentstemons which had passed through the winter in the open borders, and very interesting they were as hardy garden plants for the flower garden; but I did not find any of them worthy to be compared with the October-flowering garden varieties. I say October-flowering advisedly, because the flowers are much more valuable in that month, the beauty of the flower garden having by that time well-nigh departed. A dazzling display might well be obtained during the months of August and September; but if the same plants are expected to flower in October, the seed-pods should be removed as soon as formed, else, if they are allowed to remain, the plants become too weak to flower so well in October as in the two previous months.

The culture of Pentstemons presents no difficulties, and the plant itself ought to be hardy, at least, so far as it is derived from *Pentstemon gentianoides*. Humboldt and Bonpland found it rather more than half a century ago, "in cold situations on the sloping sides of the mountain of Toluco (whose summit is covered with perpetual snow), at an elevation of 11,500 feet above the level of the sea." Lindley, describing the plant in the *Botanical Register* for the year 1838, t. 3, says, "10,500 feet above sea-level." He also states that "the plants will stand out all the winter unprotected, but generally suffer very much from the wet." That is the reason they do not stand the winter well out-of-doors in Great Britain, and why many other plants, which a knowledge of their habitat would lead us to believe should be quite hardy in the open, succumb to our winters. The wet and frost together make sad havoc with them, whereas, on their native mountains, although the cold is more intense, the plants are covered at the time thickly with snow. It is generally supposed

that the parentage of the garden *Pentstemon* may be traced to *P. gentianoides*. This, I believe, is quite correct, so far as the deep red, rose, crimson, and scarlet varieties are included. The flowers which belong to those colours are differently formed, and droop more than those of other species. The corolla is longer, rather more slender, and the mouth does not open so widely. The arrangement of the flowers on the spikes is rather different from that of the varieties with purplish flowers. The variety figured in the *Botanical Magazine*, t. 3661, is evidently a good garden form, the flowers a rich scarlet-crimson colour. I fancy that the varieties with shorter corollas and more open flowers, with shorter peduncles, have been derived from *P. campanulata*, also a native of Mexico, but introduced into British gardens about the closing years of the last century by Sir Joseph Banks. Probably the two species have also been hybridised in gardens, and together have produced the very varied colours now possessed by the garden varieties. I am indebted to Mr. Forbes, of Ilawick, and Messrs. Stuart & Mein, of Kelso, for collections of the best varieties cultivated by them, the colours ranging from white with a faint tinge of pink and lilac to deepest purple, crimson, and scarlet. A long list of names might be thought tedious; but after carefully looking over the collections in the third week of October, I found the following to be the best at that time:—Walter Scott, a vigorous plant, producing an immense spike of well-formed, reddish-purple flowers, the throat white, blotched on the lip dark purple; Mrs. Chaplain, delicate purple; Mrs. Rae, rose, white throat; Mrs. Grieve, rose, well opened white throat; Jas. Fairbairn, bright deep rose, white throat; Mrs. Tait, purplish-rose crimson, blotch on the lip; Mrs. Gladstone, deep pink, darker blotch in the throat; Eclipse, deep rosy-red, rich maroon throat; Alphonse Daudet, rosy-crimson, the throat prettily veined; Mrs. Page, a lovely scarlet colour; Pyramide, lilac and white—fine; John Duncanson, crimson-scarlet, white throat—fine; A. McCullum, reddish-crimson, maroon blotch; Conspicua, lilac, purple and white; Mrs. Bosanquet, purplish-red; Matthew Young, Mont Blanc, and Olivier de Serre have a striking family likeness—white, with a faint rosy blush; L. Borda, rich purplish colour, maroon throat. The above are the cream of the collection, although many others should be named; but I purposely left it until very late, so as to ascertain the best varieties for standing frost and wet.

We put in the cuttings of Pentstemons a few days ago, as we like to have very late flowering plants, and the later the cuttings are struck, the later the bloom. The cuttings are inserted in sandy soil, and they are sometimes merely covered with hand-lights; but for the last few years I have found it to answer better if we use boxes of a compost of two parts loam, one of leaf-mould, one of rotted manure, and one of sharp sand. There are always plenty of suitable young growths on the plants, and these are taken off just under a pair of leaves, and inserted firmly in the boxes. The cuttings strike under the same conditions as shrubby *Calceolarias*, and may be wintered like them in cold frames. In spring, they are planted out in other boxes, and at wider distances apart, and, finally, planted where they are to flower in the month of May. If planted in beds or patches, 18 inches should be allowed from plant to plant, and the soil should be worked to a good depth and well manured. The plants will, with good cultivation, grow to a height of 3 feet, and produce numerous flower-spikes. *J. Douglas.*

DAWPOOL.

NEAR the ancient Norse village of Thurston, on the low red sandstone hills, which afford a full view of the estuary of the Dee, lies the residence of T. H. Ismay, Esq., called Dawpool. The situation is exposed to strong westerly winds. Trees are scarce in the neighbourhood, the hills being clothed with Heather and Gorse. The soil is sandy and shallow, but in the low-lying parts large deposits of boulder clay exist. In such a situation as this it is necessary

to afford efficient protection from the strong gales which frequently blow from the sea. The gardener, Mr. Bryers, finds that hedges are better than walls as wind-breaks.

A belt of mixed trees protects the lawn; inside this are a number of good standard Tea Roses, doing well. In the centre of the lawn is a pair of Hodgkin's Holly, about 32 yards in circumference. Hollies thrive very well here. The terrace wall in front of the hall is covered with choice flowering shrubs, such as *Ceanothus*, *Berberis*, *Cotoneaster*, *Gum Cistus*, &c.; the roots of each are in a chambered space, to keep the plants dwarf, and encourage flowering. A steep bank, facing north-west, is clothed with mixed *Pernettya mucronata*, full of berries, and the rock where it crops up to the surface has been planted with *Skimmias*, *Heaths*, *Cotoneasters*, *Andromedas*, *Salins*, &c. Clumps of *Rhododendrons* and *Heaths* insensibly merge into the *Gorse* and *Heather* of the hills. A drive, about half-a-mile, has been planted with *Austrian Pine* on the windward side, but although the protection thus afforded will be good, the effect will be monotonous, unless other coloured evergreens are planted between.

Greenhouses.—The houses are very substantial structures, the foundations of stone, with sheets of lead betw. it and the woodwork, the paths covered with red tiles, and a supply of water laid on.

The Vines are bearing good crops—*Madresfield Court* grafted on *Hamburg*, and *Muscat of Alexandria* on *Sweetwater*; *Alicantes* on own roots.

The orchard-house contains a number of good standard and pyramid Peaches, Nectarines, and Plums in pots; the pots are plunged, but the roots are not allowed to ramble outside. Trained Peaches on front and back; the former stopped at about 2 feet from the wall to let in sunlight to latter.

Poinsettias are largely grown; cuttings put in in March, and grown in cool house until October, when they are removed to the stove, which is furnished with large tank, through which hot-water pipes flow to give bottom-heat.

Chrysanthemums are used to decorate the vineries in winter; they are grown in 10-inch pots, cut back once to 2 inches, and subsequently pinched; when the flower-buds appear, top-dressings of *Standen's manure* are used—by this treatment, dwarf plants, bearing several large flowers, are formed.

A fernery, furnished with a tank, with thick plate-glass front, containing fish, looks very effective, but the fountain, with a pair of terra-cotta figures bearing an umbrella, seems out of place.

Fruit-room, potting-sheds, &c., are built of stone, with concrete floors, and teak-wood shelves, and fitted with electric light. *F. I. D.*

ROUND BIRMINGHAM.

HIGHBURY, MOOR GREEN.—Standing in its own grounds of rather more than 30 acres in extent, the fine residence of the Right Hon. Joseph Chamberlain, M.P., is a prominent object, and the gardens with which it is surrounded form a centre of attraction to all interested in gardening, and especially cultivators of Orchids. In the management of the gardens, Mr. W. Earp has ably succeeded the late Mr. Cooper; and in the culture of the Orchids, Mr. H. A. Burberry, during the few years he has held the office, has succeeded in putting the stamp of good culture on them all. But in every part of the garden the guiding spirit of the master is evident, it being almost his only pleasure. On the occasion of our visit, he was kind enough to accompany us on our tour of inspection, and it soon became evident that he had an intimate knowledge of every specimen, its history, and, in many cases, interesting stories to tell of the battles which were fought before it could be subjected, and induced to grow well and flower properly, as civilized Orchids should.

The garden, which was laid out by the late Mr. Milner, has a few fine old trees, whose numbers,

however, are slowly diminishing. Already a fine Beech, in a spot where it was much wanted, has gone, and another is but barely existing. The same sort of decay of old trees is going on in many places, and the new systems of town drainage seem to be the more probable cause of it. One grand old Yew at Highbury has a pleasant nook arranged for it, and it is carefully looked after, for it is of special interest, as being one of two in this district mentioned in *Doomsday Book*.

Looking from the high ground, just below the mansion, we see the undulating grass-clad gardens with their banks and borders of shrubs, shelving away to the pretty aedge-bordered lake below, on an island in which the moor-fowl and others make their home. A winding walk runs around the gardens, sometimes by banks of shrubs and stately Conifers, and sometimes alpine rockeries and ferneries, and beneath the branches of trees, whose variety of foliage at the present season give even more beautiful tints than do the summer flowers. For the purpose of coloured foliage, the *American Maples* have been largely planted, and the yellow-leaved *Retinosporas* are thrifty plants, although many other Conifers do not succeed. Beside the walk which traverses the gardens, herbaceous and alpine plants are plentifully planted, as on these the outdoor display mainly depends, *Pelargoniums* and summer bedding plants being confined to a few beds near the dwelling. Beyond the rosery is a pretty model dairy; and on all sides charming views open up, in which the dark green of the Hollies contrasts well with the bright yellow and red of the autumn tints of other trees.

The Orchid-houses.—These and other houses form a block of some thirteen or fourteen apan-roofed buildings connected by a corridor, which runs from the dwelling, and by a lofty warm conservatory and rockery planted with Ferns, and terminated with a *Dendrobium* and other Orchid-houses. The wall of this connecting corridor is utilised as a back for the large lean-to *Odontoglossum*-house and the smaller *Masdevallia*-house. The conservatory, corridor, and principal houses are lighted, when necessary, by electric light, and the whole block is so conveniently arranged that any part may be visited from the house without once going into the open air. Few more beautiful walks can be imagined than that in the lofty conservatory, with its tall specimens of Palms and Tree Ferns, and passing through the cool Fern-clad rockery, and along the corridor or covered way, from the roof of which depend bright flowers of the *Passifloras*, *Habrothamnus*, *Jasmines*, *Lapagerias*, *Plumbagos*, and other climbers, which are planted in the narrow borders beneath, and in which are graceful Ferns and *Eucharis*, *Ixoras*, and other flowering plants. Some few Orchids, too, are grown in this corridor. Here is a strong tall plant of *Sobralia Cattleyæ*, which, after its fashion, grows on and on, but never flowers. On the roof, the varieties of Mexican *Lælias* and *Barkerias* are found to thrive well at certain stages of their growth, but during the summer they are kept in one of the sunny fruit-houses.

The first Orchid-house entered showed a superb lot of *Cattleyas* and *Lælias*, equal to any in the country for vigour, and for the healthy, hard sharp-edged foliage, which bespeaks continued health and vigour. Quantities of *Cattleya labiata vera* of various importations were flowering, and exhibited the usefulness and beauty of the species. *C. Gaskelliana*, too, is well liked, and the long period of its flowering is not its least recommendation. A fine white form of it, and of *C. Mossii Wagneri*, are in the Highbury collection. One large specimen of *C. Trianae alba* had ten flower sheaths, and many large specimens of other rare species or varieties were noted. Hybrid *Cattleyas* and *Lælias* seem to get a good deal of attention, and among them are to be found most of the rare or showy varieties, as *C. Chamberlainiana* × *C. Brymeriana* × *C. Sororia* × *Lælia exoniensis*, &c.; and in some home-raised seedlings, between *Lælia cinnabarina* and *Cattleya Lawrenceana* and other promising combinations, the

Highbury collection contributes to garden Orchids that which seems now to be expected from any establishment of note. Specially remarkable in the first *Cattleya*-house were *Cattleya Bowringiana*, with numerous flowers on strong spikes; some healthy plants of *Compactia*; nice tufts of *Sarcophilus Hartmanni*, and other small-growing species, which thrive here admirably, suspended close to the glass.

In the first division of the next range, suspended from the roof, was a grand collection of *Phalænopsis* with large leaves, and numerous aerial roots, the whole forming a sight rarely seen; for in most collections the *Phalænopsis*, which here thrive so well and flower so profusely, refuse to be comforted, although they be tried in every possible manner. *P. Schilleriana* and *P. amabilis* form the chief part of the collection, but many other species are grown, and all do well. In the next division, *Aërides Lawrenceana* and *Miltonia Roezlii* were doing well, as also a number of plants of *Angræcum Sanderianum*, a great favourite here, and which were showing profusely for bloom.

The next is an intermediate-house with a good show of flowers of *Cattleya maxima*; here a grand form of *Lælia elegans Schilleriana*; a splendid show of *Odontoglossum grande* and *Vanda carulea*, with exceptionally large flowers; a pretty and graceful sprinkling of plants of *Dendrobium Phalænopsis Schroderianum*, *D. bigibbum*, and some of the elegant *Oncidium incurvum* were observed. Plants of *O. Forbeaii* were furnished with very massive spikes; also *Lælia Dayana* and *L. praestans*; some fine white and orange-flowered *Dendrobium formosum giganteum*, *Cattleya aurea*, *C. Dominiana* ×, and other species, the whole being cleverly arranged and interspersed with Ferns.

In the *Odontoglossum*-house, the appearance of the plants maintained the high standard found in the other houses, the plants of *O. crispum* and *O. Pescatorei* being in first-rate condition. Along the roof were hung a number of *Odontoglossum Rossii majus*, *O. Cervantesii* varieties, and the pretty scarlet *Cochlioda Noetziiana*. In the Mexican *Lælia*-house, the white and coloured *L. anceps* were observed to be well furnished with flower-spikes. Among the coloured ones, *L. a. Chamberlainiana* is the largest and brightest-coloured variety known, and *L. a. Highburyensis* is very remarkable; *Lælia Gouldiana*, too, and other species are about to flower.

The next is the house of the lesser-growing *Cattleyas*, *Miltonia vexillaria*, *Cœlogyne cristata*, *C. c. alba*, &c. Then comes a house in which the plants of *Odontoglossum citrosum* were superb, and the *Lycastes*, *Oncidium tigrinum*, &c., equally good. After that the collection of showy *Masdevallias* follow, and so on through all the general run of showy Orchids, until we came to the *Dendrobiums*, which, with the *Phalænopsis*, the *Cattleyas*, and *Lælias*, and the *Odontoglossums*, may be said to be the pride of the collection. The *Dendrobiums* are arranged in two houses, one at present holding the bulk of those at rest, and the warmer one the plants of *D. Phalænopsis*, *D. bigibbum*, and others of that class; and these grow here to unusual proportions, and flower most satisfactorily. One plant of *D. bigibbum* had a very thick pseudobulb 2 feet 9 inches in length, and it might easily have been mistaken for *D. superbiens*. *Cattleya Lawrenceana* and *C. Massiana* do well in this house. The *Dendrobium Wardianum* and *D. nobile* varieties have extraordinary growths; and *D. Venus* ×, *D. Casiope* ×, *D. Leechianum* ×, and other hybrids, seem even more easily grown than the species.

And now, perhaps, the question will be asked, "What about the *Cypripedium*?" Well, the truth must be told: they are not liked. It is true that that wonderful new species, *C. Chamberlainianum*, was named in honour of Mr. Chamberlain, and that the best piece of it imported is to be found there, but the rest are conspicuous by their absence. However, *chacun à son goût* is well understood among orchidists, and each, as a rule, goes on his own way rejoicing.

Having left the Orchid-houses, we passed through those that contained Camellias, Azaleas, &c.; the pretty Fern-house, with its hanging-baskets of Maidenhair; the stove-house, bright with scarlet-spathed Anthuriums; the Cyclamen and Primula-house, the large Tea Rose-house, the long range of fruit-houses, sheltering a vast army of fine Chrysanthemums, and so we passed out, well pleased with what we had seen and heard.

(To be continued.)

SCOTLAND.

DUPLIN CASTLE, PERTH.

It is not uncommon, when travelling by railway to Perth from the west, to hear passengers comment strongly on the long stretches of glass and spacious

form an imposing picture, with the river Earn (then much swollen by the rains) sweeping along the strath. Mr. Browning, the head gardener, was from home, but a representative who knows all that is necessary to enlighten a visitor, was easily found. A long range of houses, somewhat narrow, and about 500 feet in length, was entered, in which fruits and Roses (for early blooms) are extensively grown. Alicante Grapes were first-rate in every respect, and would grace any exhibition table—Mrs. Pearson and Golden Queen were in good condition. Muscats and Mrs. Pince are largely grown, and fine in bunch and berry.

In the Peach-houses, the back walls are clothed with healthy trees; Bellegarde and Walburton Admirable are in great favour. The fronts of these houses are used for Tomato-growing, where they produce abundant crops; Austin's Eclipse is noticeable for its free-cropping proclivities and its fine

flowering) was entered, and we then emerged into a plant-stove, in which are numerous table plants and flowering species for winter supply. Dendrobium nobile and Jamesianum, Maxillarias, and Cattleyas are among the leading species. Cypripediums were numerous and healthy, and some were throwing up their flowers. C. insigne occupies much space, and is much valued. C. Sedeni was flowering freely, Pancratiums, Crotons, Eucharis, and other plants were also in luxuriant condition. A Cucumber and another Tomato-house were passed through, meeting the requirements with plentiful supplies; another structure was filled with Begonias of nearly every shade of colour. Then a small house, with Odontoglossums (chiefly Pescatorea and Alexandræ) and Masdevallias, was inspected, where all the inmates are in capital condition. Lapageria rosea and alba were in great profusion of bloom overhead in corridors, and of much value for table work. Heliotropes,

FIG. 80 - VIEW OF DUPLIN CASTLE, PERTH.

walled-in gardens which, on the face of the hill, near Forteviot, are landmarks of no ordinary kind. I wended my way to inspect them, and found much in this fine garden to render my hurried visit a profitable and enjoyable one. The view alone from the front of the main range of glass is so grand that one feels amply repaid for a journey to Duplin, the splendid seat of the Earl of Kinnoull. In the south, east, and west, scenery of the most attractive description meets the eye. The numerous seats along the northern side of the Ochil hills form a beautiful and continuous landscape. The hill of Moncrieffe is very striking, and at the base is the pretty seat of the Moncrieffe family. Rossie, a rising place of horticulture, is seen adjoining the finely-wooded domain of Freeland, of Orchid fame, and westward, the romantic and picturesque grounds of Inverary are conspicuous, and many of the fine seats in Strathearn are readily descried in the distance, which

appearance, and is undoubtedly one of the best. Long lines of zonal Pelargoniums line the sides of the paths, and are valued for decorative purposes. Figs on back walls were in most fruitful condition; Brown Turkey and White Marseilles appear to be most in favour. Camellias are grown extensively, and are loaded with flower-buds; the old double white is in special favour. Foliage itself is attractive on many of the fine plants. Greenhouse Rhododendrons and Azaleas are extensively and well-grown.

Passing by several small structures, the Gardenia-house was entered, where an attractive collection of choice plants is loaded with open and opening flowers. The foliage on the huge specimens was in perfect health and thoroughly clean. The plants are planted out in a bed, and are most serviceable. G. florida appears to be much in favour, and is one of the freest-flowering varieties. Passing down a corridor, a Rose-house (chiefly for winter-

habrothamnus, and other free-flowering plants cover available spaces on back walls of plant-houses. Passing onward, Chrysanthemums are seen in great numbers. Single Dahlias, Antirrhinums (a fine strain), and Dobbie's choice Violas (among numerous species of decorative plants in borders) were remarkably attractive. The vegetable garden, which slopes very steeply to the south, partakes largely of the ornamental as well as the useful, and about 10 acres are enclosed with walls. The moist season appears to have suited vegetable-growing at Duplin, every available space being closely cropped with fine culinary produce. Apples and Pears were scarce, but Apricots (the crop was gathered) had been a fine show, and such a long wall covered with healthy fruit-bearing trees is very creditable indeed; the position at the head of the slope appears to suit them remarkably well. Much more could be written on these fine gardens, and also of the grounds (in which

are fine Coniferae and other arboricultural treasures), which form one of the finest seats in Perthshire, and it is very pleasing to visit an extensive place in such fine order, and one which throughout reflects much credit on Mr. Browning's skilful management. *M. T.*

A MYSTERY SOLVED.

For the past fifty-three years, a curious production has been known to mycologists as occurring buried in the ground in Australia, and known to the colonists as "Native Bread." In 1839, Berkeley described it in the *Annals of Natural History* (p. 326) as *Mylitta australis*, under which name it was figured by Corda in his *Icones Fungorum*. Although no fruit has ever been discovered, there was a suspicion of its being related to the Truffles, from the fact of its being subterranean, and from the mottled appearance of its internal substance. It has often been found as large as a child's head, but when dry it is as hard as a stone. Latterly, there have been many insinuations of a suspicion that this production was nothing more than a large sclerotium, a suspicion now proved to be true. Nearly twelve months since I was informed that a specimen had been found with a Mushroom growing from it; and now that a specimen has been sent to me with the fungus growing upon it, the whole mystery is clear. The sclerotium or *Mylitta* was about 6 inches in diameter, and from it was growing a pure white *Polyporus*, closely allied to *Polyporus ovinus*. In the present instance there were two individuals growing so closely together as to appear but one and the pair almost as large as a man's fist, perfectly white and fleshy, but becoming tough when dry. The pileus was convex, almost hemispherical, and finely velvety on the surface, supported upon a short thick stem, not exceeding an inch in length. The tubes of the hymenium 7 millimètres long, and the angular pores about half a millimètre in diameter, with an acute edge. It is intended to describe this new species fully and technically under the name of *Polyporus Mylitta*, Cooke and Massee but such an interesting discovery should be made known at once. The specimen above alluded to was found in South Australia, but we have heard of another in Victoria. *M. C. Cooke.*

FORESTRY.

LAND PREPARATION, DRAINAGE, &c.

As a general rule, trees have now matured their growth for this season, and when the young wood becomes hard and firm, the trees may be lifted and planted out where they are to remain. In view of such circumstances, the fencing, draining, trenching, and other preliminary work in advance, should now command the planter's attention, so that no time may be lost when the proper time for planting out arrives. I need hardly say, that the draining of wet ground should take precedence of all other operations, the number and size of the drains required to be made will depend on local circumstances, and must always be settled on the spot. I may, however, state that I have occasionally seen a large area of ground kept almost in a quagmire by a single spring, and when such is the case, the spring should be tapped at its source by cutting a drain large enough to carry off the water at any season; and should other wet spots occur here and there along the line of this drain, small branch-drains should be cut of sufficient number and size to render the surface dry and firm. This branch of forestry requires to be well studied and carried out before a plant is put into the ground.

Plantation drains should always, if possible, be kept open, as pipe or tile drains are almost sure to become choked up with tree-roots in course of time, and thus create a great deal of trouble and expense. Dry ground, on the other hand, that is resting upon a hard subsoil of moor pan, should be broken up with a pick at the spots where the

trees are to be planted, but in cases where hardwood trees are to be used of a pretty large size, capacious pits should be dug so as to allow the roots to be spread out to their full length without crossing each other. The spots that are loosened with a pick may be planted with small Coniferae by the "notch" system of planting, which is a great saving of labour and expense.

PLANTATION ROADS.

In the formation of plantations of any great extent for ornament and utility combined, it is necessary to lay out roads, and this can be done best whilst the ground is unplanted. The size of these roads may vary to taste and local circumstances; but roads 24 feet wide, so that two vehicles can pass each other with freedom, will be found to give general satisfaction. As a general rule, these forest roads do not require to be macadamised—a small ditch cut along either side of the road, and some loose material laid on the centre of the road to raise it a little above the sides, so that the water may run off into the ditches will suffice. Where the surface is loose and open, sow the seeds of some hardy grasses with deep spreading roots, which in due time will render the surface firm and passable. *J. B. Webster.*

THE BULB GARDEN.

NARCISSUS BIFLORUS.

This late-flowering variety is well worthy a place in the mixed border, as it prolongs the display of these flowers, both for cutting and for decoration, where growing. Its pleasant perfume is a point in its favour, especially as a cut bloom. It is one of the species of *Narcissus* which will go on increasing for years in the same place if left alone, which is a great advantage, as it saves the troublesome job of lifting after ripening. *E. M.*

FLORISTS' FLOWERS.

DAHLIAS.

On paying the nursery of Mr. M. V. Seale a visit recently, where Dahlias are largely and well grown, many novelties were noted which were quite fit for exhibition. The finest of the doubles were R. T. Rollinson, Mr. Gladstone, Glow-worm, Mrs. Langtry, Mrs. John Downie, Mrs. Saunders, Hugh Austin, and Prince Bismarck. In fine single-flowered varieties were Guliema, W. C. Harvey, Duchess of Albany, Miss Jellies, James Scobie, Albert Victor, and Northern India, all of which are of great merit. The Cactus formed a grand section, some of the best being St. Catherine, Baron Schroder, Kyneth, Duke of Clarence, Delicata, Caonell's Favourite, Robert Mayhew, Harry Freeman, and Professor Baldwin. The noticeable Pompon Dahlias, some of which were at their best, were Admiration, Phoebe, Lilian, Leila, Whisper, Lady Blanche, and Margery, a salmon-red, a free bloomer, and with good habit, *R. Edwards, Beechy Lees, Oxford.*

THE WEEK'S WORK.

THE KITCHEN GARDEN.

By G. WYTHES, Gardener, Syon House, Brentford.

DIGGING AND MANURING.—When charred rubbish is to be obtained in quantity, it is a valuable fertiliser to be dug into the soil at this season, and is a capital substitute for stable and farmyard manure. When these have been much employed, the soil of gardens long under cultivation is generally too rich in vegetable matter, and good results are sure to follow the use of burnt materials and of lime. The fertile portion of the soil is the surface, and in digging and trenching it is not wise to turn this to the bottom, and let its place be taken by the soil poor in organisms from the subsoil, and the practice is far worse than shallow digging. The deep cultivation of the land, and the retention of the best

soil at the surface, may be carried out at the same time. Vacant plots of ground should not be allowed to lie fallow, but manured at the earliest moment, if manure be required by the kind of crop that it will carry next year, and be trenched or dug, tidying it, or, in any case, leaving it in a rough state. Manure-heaps should be turned, the sides into the middle, and be put up fair and square, the roughest and least decayed portion being got well below the surface. Fresh rubbish and crop clearings may be got into a condition fit for use by mixing lime in a fresh state with them in process of turning. If manure-heaps are small, a covering of soil should be laid on top and sides, to prevent in a measure the loss of ammonia. To light land add loam and burnt soil, and even clay will be of benefit if spread on the surface for the frost to act upon it, and then be forked into the staple. Chalk and lime should now be spread on land deficient in lime, and especially where stone fruits are grown.

CLUBBING OF CABBAGES, ETC.—The free use of lime and chalk will diminish the loss of plants from this cause; gas-lime is also of much benefit, if not applied too heavily. It is best to spread it evenly, and allow it to lay on the land for a few weeks before digging it in. Gas-lime should be broken up quite small before it is dug into the soil. As a remedy against wire-worm it is very effective, and the good uses of soot and fresh-slaked lime are well known. Peruvian guano, superphosphate of lime, and nitrate of soda applied to the soil in winter, if much infested with injurious insects, are of great service.

PLANTS UNDER GLASS.

By R. MILNER, Gardener, Penrice Castle, Swansea.

THE PLANT STOVE.—The temperature of this house should be slightly reduced to 65° and 75° by day, according to the state of the weather and the outside temperature; and at night 60° or 65°. When affording air and a little fresh air should be admitted every day—much care should be exercised, admitting it as early in the morning as the weather permits, and closing the ventilators soon after noon, so as to shut in a quantity of the sun's heat. Keep the foliage of all plants required for furnishing purposes clean by frequent sponging it with clear water; and if the smaller specimens of *Dracenas*, *Palms*, *Crotons*, *Pandanus*, and others, be infested with the white or the brown scale insects, special attention should be given to well cleaning them of these disfiguring insects. Most summer-flowering plants, as *Allamanda*, *Clerodendron*, *Stephanotis*, *Bougainvillea*, *Dipladenia*, should now be in a state of rest, or suspended growth, and may be placed together at one end of the stove, so that they can have similar treatment. These plants should not be allowed to get dust dry, or the wood will shrivel, which is usually an injury to the plant, but sufficient water should be given, at intervals, to preserve the plumpness of the wood—more than that is not necessary. If *Stephanotis* is wintered in a cool-house, as some are, less water is needed. Specimen plants of *Ixora* which have ceased to flower should also be kept drier at the roots, and in a little lower temperature. The young stock of *Ixoras* will now be growing freely, and should be kept in a light position to prevent weakly growth of shoots and leaves; and such shoots as are taking an undue lead should have their point pinched out, which will throw strength into the weaker ones. Large plants of *Croton* which have got straggly should be kept dry at the roots for a few days preparatory to their being headed back. They will be, after this operation, made shapely plants. After the cutting-back is done, the pots containing the plants should be plunged in heat, and if the bed consists of hard tree leaves, so much the better. A light overhead syringing with tepid water should be afforded these plants every morning to induce a good break; and afford but little water at the roots before the young shoots have fully appeared. Mealy-bug usually infests *Crotons*, and a sharp examination should be made frequently, and if any of these insects are discovered, remedies must be at once taken against them, and this is the more easily done while the plants are sparingly furnished with shoots.

FRUITS UNDER GLASS.

By J. RIDDELL, Gardener, Castle Howard, York.

FIGS.—If the houses in which Figs are grown are specially devoted to this fruit, they should undergo the same thorough kind of cleansing as that recommended for vinerias and peacheries. Thin

out as much of the old wood of the Fig trees as circumstances will permit, and all small twiggy growth which is not required to cover the trellis of trained trees; reduce the number of shoots of the current year's growth to what is necessary to cover the allotted space, so that they stand at from 4 to 6 inches apart, retaining always those which are the best ripened and best placed to form the groundwork of the tree, those which are intended to supply the first crop, and those growths which will yield later fruit the following year. Any very gross shoots should be cut well back, or removed entirely. The shortening of young growths, however, should be avoided in all cases when they have attained maturity, as it is from them that the first fruits will be taken. When large plants have been allowed to throw up suckers freely from the root, and these have been laid in to form part of the tree, the plants in time will consist entirely of these unfruitful branches, and the present time may be utilised in altering this undesirable state of things, by removing as many of these branches as can be spared, and spreading out the others to fill the space occasioned by their removal. By first taking off the lower branches on each side of the centre, and allowing the one nearest that point to make as much growth as possible during the growing season, the plants in a few years can be got to stand on single stems, and in this form they will be found more fruitful than they have been. Figs grown as standards or bushes should also have their weakly wood cut out, and their fruiting shoots thinned to 6 inches asunder. Nothing is gained by crowding these, and when the plants have occupied the space at command, the longest branches may be removed, if there are younger ones to succeed them. In clearing the plants of scale or red-spider, nothing beats a stiff brush and Fir-tree oil. The brush lifts the old scale which covers hundreds of its progeny, and enables the oil to destroy them. After re-tying these plants on their trellises, another good dressing of this insecticide may be afforded them by means of a syringe. I may here state that this insecticide is most efficacious when applied in a hot state, and the water used free from lime or other minerals. One or two applications between now and the time of starting to force will be of great benefit in checking the spread of these insects. Remove the surface of the border, and top-dress with a mixture of friable loam and lime, or lime-rubbish, and afford a slight watering if the soil is dry. On no account, however, indiscriminately soak the border, or more harm than good will be done. Keep the atmosphere cool and airy, and admit a few degrees of frost, if this can be done without risk to the heating apparatus, or other occupants of the house.

THE ORCHID HOUSES.

By H. A. BURBERRY, *Orchid Grower, Highbury, Birmingham.*

AN INSECT ENEMY TO DENDROBIUMS.—A species of beetle, not large, but apparently large enough to be capable of destroying valuable Dendrobiums, has made its appearance in collections, causing Orchid-growers much uneasiness. They have already enough reason to complain of the greatness of the number of the enemies to their plants. The short space of time which has elapsed since my introduction to this last recruit prevents my speaking authoritatively on the subject, but my experience, such as it is, I hasten to give, fearing that the pest may possibly be busy at work in somebody's collection unobserved. The beetle, according to present knowledge, seems peculiar to the Dendrobiums of North Australia, and those generally belonging to that section. It was discovered here on *D. biggibum*, and a further search resulted in its being found on *D. Phalaenopsis*, *D. Phalaenopsis Schroderianum*, *D. superbiens*, *D. stratiotes*, and *D. Dalhousianum*, the last-named being the most severely attacked. All of the specimens found are of the same size, being about half the size of an ant, resembling too, the ant in colour, and when seen through a strong lens, they look like an ordinary black-beetle. They are very slow of motion, but it may be they are not fully developed, and their movement in the adult stage may be livelier. Their presence is indicated by small cleanly eaten holes on the pseudobulbs, which look like the holes seen in worm-eaten furniture. If these holes escape notice, the yellowing of the leaves and the shrivelling of the pseudobulbs for about an inch above and below the hole will show that something is wrong; and on cutting the pseudobulb open a nest or small cavity will be found, containing one or more of the beetles, and the surrounding tissues

will be quite decayed. It is an open question whether the holes are first pierced by the adult beetle, and the larvæ deposited therein, or whether they are hatched in the pseudobulb and afterwards eat their way out of it, as in the case of the Cattleya-fly. I incline to the former theory. It would be interesting, however, to have the experience of other growers on the subject, and information as to its first appearance in this country, and whence imported. If allowed to propagate unchecked, this beetle would doubtless become a source of great annoyance to orchidists; but there is, at present, little cause for alarm, as the pest will, in all probability, soon be stamped out if proper precautions are taken. I would advise an examination of the plants, and if indications of the beetle are found, to cut the pseudobulbs, and burn them, and for that matter the whole plant might be burnt if badly infested; and all other plants cleaned with some proper kind of insecticide.

THE FLOWER GARDEN.

By H. W. WARD, *Gardener, Longford Castle, Salisbury.*

ROSE-PLANTING.—In continuation of my remarks in the previous week on the planting of Roses, I now give a select list of varieties of the various classes of Roses. They are what is understood as garden varieties, in contradistinction to those which are essentially show Roses, being of good habit, strong constitution, and profuse bloomers, and handsome withal.

BOURBON ROSES.—Acidalie, white, tinted rose, very beautiful; Armosa, clear, bright pink—an old but excellent Rose, of China Rose-like habit; a constant-blooming variety. Catherine Guillot, very bright carmine-rose, free bloomer, and good habit; Queen of Bedders, deep crimson, and very free-flowering; Rev. H. H. D'Ombraïn, bright carmine, large, and of good form; Souvenir de la Malmaison, pale blush, very large—a fine free-blooming autumn Rose; a time of year when the Bourbon Roses produce their finest blooms.

CHINA ROSES.—American Banner, flowers semi-double, yellowish-white, with broad, rose-magenta stripes—very free-flowering; Archduke Charles, rose, changing to deep crimson; Clara Sylvain, pure white, large; Cramoisi Supérieur, brilliant crimson; fine for beds; Ducher, pure white, medium size, full and well formed, growth vigorous, fine for massing; James Sprunt, deep crimson, pretty shape, of moderate size, a distinct, climbing-habited sport from Cramoisi Supérieur.

HYBRID CHINA ROSES.—Blairii No. 2, pale blush, very large and double; Coupe d'Illebé, waxy-pink, beautiful; Fulgens, bright crimson-scarlet, superb; Juno, pale rose, very large; Madame Plantier, pure white, in large clusters; Paul Verdier, very bright rose, large, full, and fine shape, and very vigorous.

HYBRID PERPETUALS.—A. K. Williams, bright carmine, red, large, round, imbricated flower; Alfred Colomb, bright red, full and very showy; Auguste Rigotard, bright crimson, large and good; Bessie Johnson, blush-white, large, very sweet, and good habit; Captain Christy, delicate flesh colour, deeper in the centre, very effective; Charles Lefebvre, fine, bright, dazzling crimson-scarlet colour, and form very good; Comtesse d'Oxford, brilliant carmine, very large and full, of fine form and vigorous growth; Dr. Sewell, brilliant crimson-scarlet, shaded with purple, large and full, and finely-cupped form; Duchess of Edinburgh, a fine light-coloured Rose, large, full, and well-formed; Duke of Cornwall, rich, bright velvety-crimson, with a fiery blush, free and good; Fisher Holmes, bright scarlet, imbricated; François Michelin, deep rose, reverse of petals silvery, large, full, and globular form; Helen Paul, white, sometimes shaded with pink, full, and globular; Hippolyte Jamain, fine, bright rose, shaded, with carmine, very large and full; John Hopper, fine rosy-crimson, back of petals fine lilac tint, large and full; Jules Finger, white, centre shaded with pink, growth very vigorous, flowers large and full, and perfect in form; La France, beautiful rosy-lilac, very distinct, large, and full, free-blooming; Madame Eugène Verdier, bright rose, suffused, with white, large and showy; Magna Charta, bright pink, suffused with carmine, very large, full, and of good form; Marguerite de St. Amand, bright pink, large, full, and imbricated; Marie Baumann, light crimson-red—very large and full; Mille.

Marie Rady, fine brilliant red—good form, and very fine; Miss Hassard, delicate pinkish-flesh, large, full, fine shape, and very sweet; Ulrich Brunner, bright cerise-red, large, and full.

MOSS ROSES: SUMMER VARIETIES.—Alice Leroy, blush, shaded with rose—large and double; Baronne de Wassenaer, deep rose—very large and double; Captain Ingram, dark velvety-purple—fine; Marie de Blois, bright rose—large, full, and well mossed, handsome bud; Nuit de Young, velvety-purple; White Bath, paper-white, beautiful, large, and good.

PERPETUAL MOSS ROSES.—Blanche Moreau, pure white, of perfect form, well mossed, the sepals passing beyond the bud nearly an inch; James Veitch, deep violet, shaded crimson, large and double; Madame Moreau, fine vermilion-red, veined with white—very large; Madame Edouard Osy, reddish-crimson; Perpetual White Moss, white—very pretty in the bud; Souper et Notting, fine bright rose—perfect form, very large and full. Brief lists of Noisette, Tea, and other sections of the Rose not included in the above, will be given shortly.

THE HARDY FRUIT GARDEN.

By H. MARKHAM, *Gardener, Mereworth Castle, Maidstone.*

ORCHARDS.—Now that the best time to plant fruit trees has arrived, the work, if on a large scale, should push forward, so as to get the planting finished before the very frosty weather sets in. The early planted trees, if the work is well done, usually start away freely the following spring, and make rapid progress the first year; whereas those which are planted late in the winter or in the spring make much slower growth, especially if the summer be a dry one, and the time at the disposal of the gardener does not admit of their being well watered. The planter should select and plant only the most serviceable varieties, and not too many of these. The land should be got into thorough order previously to planting. If the land is under grass (where the fruits are always better in colour) remove from 6 to 9 square feet of turf, and then throw out the top spit, breaking up the subsoil. If poor and unsuitable, it should be carted away, and the holes filled up with a better compost; otherwise, the bottom spit may be ameliorated by mixing with it road scrapings, burnt earth, and mortar rubble, and in poor soil manure should always be added to the subsoil, and also to the upper portion, the trees growing well in this kind of soil, when manure is added at first, and at intervals afterwards. The larger-growing varieties of Apples and Pears should stand from 30 to 40 feet apart; Plums at 20, and Damsons at 25 feet apart, unless they are intended as a windbreak, then from 10 to 15 feet apart will be more desirable distances at which to plant. The wider intervals between the permanent trees admit of bush or half-standard Apples, Pears, Quinces, Medlars, being planted midway between them, to be left or taken away as may appear desirable in after years. The Medlar and Quince are scarce fruits in all large towns, fetching comparatively high prices at the present day, and there is no reason why their culture should not be greatly extended. After the stations for the trees have been prepared, strong stakes should be driven into the hard bottom for fastening the trees to as soon as planted. In planting, the roots must not be too deeply buried in the soil, and it is advisable in damp soils to plant a little above the ground-level, and firm. Orchard land should be well drained, and, if possible, have a slope to the north, and the trees should be in lines running north to south. Damsons may well be used in the outermost lines, and the Farleigh Prolific is a fine variety to plant, and may be planted somewhat close together, and in that way, as aforesaid, the trees form good wind screens. The following are good varieties to plant:—Desert; Cox's Pomona, King of the Pippins, Margil, Blenheim Orange, Kerry and Ribston Pippins, Summer Golding, Wyken Pippin, Worcester Pearmain, Red Quarrenden, Gladstone, Winter Queening (for very late), Claygate's Pearmain, and Mabbot's Pearmain. These are all good, but there are many others to select from. For high colour, Baumann's Reinette, which keeps well. Kitchen varieties: Warner's King, Lady Henniker, Fillbasket, Lord Derby, Lord Grosvenor, Waltham Abbey Seedling, Lane's Prince Albert, Stirling Castle, Ecklinville Seedling, Queen, Golden Spire, Stone's, New Hawthornden, Yorkshire Beauty, Keswick, Bramley Seedling (very good), Northern Greening, Wellington, Tower of Glamis, Alfriston, &c.

APPOINTMENTS FOR THE ENSUING WEEK.

MEETINGS.

- TUESDAY, Nov. 1. Royal Horticultural Society Committees meet at Drill Hall, James Street, Westminster.
- FRIDAY, Nov. 4.—Dundee Horticultural Association.

SHOWS.

- TUESDAY, Nov. 1. Royal Horticultural Society, at the Drill Hall, James Street, Westminster. Prizes for Chrysanthemums, &c.
- WEDNESDAY, Nov. 2. Chrysanthemums at Croydon, Portsmouth, Ascot, and Edling (two days).
- THURSDAY, Nov. 3. Chrysanthemums at Hertford (two days). Steyning and Romford (two days).
- FRIDAY, Nov. 4. At Bolton, Chrysanthemums, Plants, Fruits, &c. (two days).

SALES.

- MONDAY, Oct. 31. Dutch Bulbs, Lilies, Plants, &c., at Stevens' Rooms. Bulbs and Plants, at Protheroe & Morris' Rooms.
- TUESDAY, Nov. 1. Dutch Bulbs, Lilies, Plants, &c., at Stevens' Rooms. Dutch Bulbs and Orchids, at Protheroe & Morris' Rooms. Annual Sale at Hale Farm Nurseries, Tottenham, by Protheroe & Morris.
- WEDNESDAY, Nov. 2. Dutch Bulbs, Lilies, Plants, &c., at Stevens' Rooms. Sale of Nursery Stock, at Hickmandias Nursery, Knockholt, Kent, by Protheroe & Morris. Dutch Bulbs, at Protheroe & Morris' Rooms.
- THURSDAY, Nov. 3. Sale at Lee's Nursery, Isleworth, by Protheroe & Morris (two days). Dutch Bulbs and Plants at Protheroe & Morris' Rooms.
- FRIDAY, Nov. 4. Sale of Orchids and Dutch Bulbs, at Protheroe & Morris' Rooms.
- SATURDAY, Nov. 5. Dutch Bulbs, Lilies, Plants, &c., at Stevens' Rooms. Dutch Bulbs, at Protheroe & Morris' Rooms.

CORRECTED AVERAGE TEMPERATURE FOR THE ENSUING WEEK, DEDUCED FROM THE OBSERVATIONS OF FORTY-THREE YEARS, AT CHISWICK.—45°·5.

Apples for Cider Making. We are, all of us, so accustomed to think of Apples as articles of food, that we do not give the great army of cider-drinkers a thought; and yet good cider would, if it were plentiful, run very hard for the first place in the estimation of many persons. It was known to the ancients; and PLINY alludes to perry and cider as a wine made from the Syrian pod, from Pears and Apples of every kind. Cider seems to have been brought into Normandy by the Moors of Biscay. It was afterwards spread through some other provinces of France, whence it was introduced into England. As a refreshing beverage with but small intoxicating powers when drunk in moderation, it should certainly have preference over the thin ales, made from we know not what, which persons, not total abstainers, ordinarily drink.

Cider Apples are divided into three classes—the sweet, the bitter, and the sour. The second are the best; they afford a denser juice, richer in sugar, which clarifies well, and when fermented, keeps a long time.

The French, who make a good deal of cider, classify some of their favourite Apples according to their specific gravity, and taking distilled water at 1000, the following varieties give the different results:—

Juice of the Green Reinette	1094
" " English Reinette	1080
" " Red Reinette	1072
" " Musk Reinette	1089
" " Foullet Rayé	1064
" " Orange Apple	1063
" " Reinette de Chaux	1060

The undermentioned varieties of cider Apples are recommended in that fine work, the *Herefordshire Pomona*, published by the late Dr. BULL, with the assistance in technical detail of Dr. HOGG:—

Ancell, or Ansell, a red, russetty Apple, much grown at Oldbury, in the Vale of Berkley, Gloucestershire. It grows erect, and bears freely; it is a late fruit, and makes excellent cider.

Alford is a white, medium-sized Devonshire variety. The tree is large and spreading, and bears freely; it is late, has a sweet juice, and makes very good cider.

Bell Orchard Seedling, or Ledbury Bell, is of medium size, in colour, shape, and general appearance somewhat resembling Foxwhelp; the flesh, which is red-tinted, has rich juice of good flavour; it makes cider of the first quality. The tree is an erect grower, very strong, and a very free bearer.

Bennett Apple is an orange-coloured fruit, of more than medium size, with sweet juice, having a specific gravity of 1073.

Best Bache, or Bache's Kernel, is an old variety much grown in south-east Herefordshire; it is of full medium size, yellow in colour, streaked with pale and dark red. It has a rich juice, of the specific gravity of the one previously-mentioned.

Broad-leaved Hereford is a large green conical Apple, with a slight flush of red on the sunny side. It makes good cider.

Devonshire Royal Wilding, or Red Hill Crab, makes a first-class cider, with great roughness and body. Five guineas have been offered, says Mr. Hugh Stafford, of Piner, in 1753, for a hogshead of it, whilst ordinary cider was fetching but twenty shillings. When cooked, the fruit has something of the rough flavour of the Quince.

Jersey Chisel is a striped bitter-sweet Apple that is in high esteem in Somersetshire. It is a constant and free bearer, making rich cider, of high colour, and if mixed with some rich sweet Apples ripening at the same time, the cider becomes of the highest quality.

Of well-known and esteemed varieties, may be mentioned—

Early Varieties.—Bran Rose, Cherry Hereford, Cherry Pearmain, Cider, Lady's Finger, Gennet Moyle, Red Splash, and Saek Apple.

Mid-season.—Bastard Foxwhelp, Dymock Red, Eggleton Styre, Forest Styre, Foxwhelp, Garter Apple, Hagloe Crab, Mun's Red, Red Foxwhelp, Red Royal, White Styre.

Late.—Black Hereford, Bromley Carrion, Cowarne Red, Kingston Black, Strawberry, Hereford, Styre Wilding, Tanner's Red, and Wilding Bitter-sweet.

Although much of our cider comes from the western and south-western parts of England, there is no reason whatever why cider Apples should not be grown in any part of the country, provided the land is of a suitable quality. It was THOMAS ANDREW KNIGHT's opinion that "Herefordshire is not so much indebted for celebrity as a cider county to her soil as to her valuable varieties of fruit." The same authority also says:—"The excellence of the cider formerly made from the Red Streak, Golden Pippin and Styre in light soils, seems to evince that some fruits receive benefit from those qualities in the soil by which others are injured."

Dr. BULL in the before-mentioned work says, "That it is a curious fact, and certainly more than a coincidence, that the practical experience of so many generations of men should show that

the two English counties which have chiefly given its high character to English cider, viz., Herefordshire and Devonshire, are both remarkable for the same character of soil, that is, for the deep clay loam of the old red sandstone. This experience is fully borne out in our own times, and even in those favoured counties, the districts specially noted for this character of soil are equally remarkable for cider of the highest flavour and quality." Although the qualities and nature of this kind of soil produce the highest results, very fair cider can be made on any loamy soil, if it be of sufficient depth, and is properly drained, should it stand in need of draining.

The growth of cider-fruit is more eminently suited to farmers than is that of market fruit, as once properly selected varieties are planted with the necessary care at the first, duly cutting them back to form a head at that time, and if the orchards are manured every few years after the trees begin to bear, or before, if progress is slow, nothing more is necessary, beyond occasionally thinning the crown, and preserving the young trees from damage by farm-stock, hares, and rabbits. The cultivator has no need to root-prune the trees, as these are certain to bear, if he wait long enough, and the severance of the anchoring roots of a large-headed tree would be a grave mistake. Grease-bands would make the trees secure against the winter moth, and a naphtha lamp would assist him to rid the trees of those destructive moths which nest in the branches.

If what we have said should induce land-owners and farmers who may read these remarks to give cider-making the consideration it deserves, we shall have helped them to carry on their contest with the present adverse conditions of farming and the cultivation generally of the land.

We have already alluded to the superb *Herefordshire Pomona*, but as this must be inaccessible to many, we may call attention to the abstract from it published by JAKEMAN & CARVER, of Hereford, under the title of *The Apple and Pear as Vintage Fruits*.

SEEDLING SUGAR-CANES.—A short time ago considerable interest was taken in the announcement made that seedlings of the Sugar-cane had been raised at Java and Barbados, and that in spite of many statements to the contrary, the cultivated forms of the sugar-cane had not entirely lost the power of producing fertile seed. Since that time, the seeds of the Sugar-cane have been observed in the glumes; they have, moreover, been fully described, and further, their germination has been so carefully observed as to leave no doubt whatever on the subject. Several hundreds of seedling canes raised at Barbados, Java, and latterly at Kew, have been grown during the last two years, and the variation amongst them, as might easily be supposed, has been very considerable. Some few have already been proved to be of especial value. Of the vigour of growth of the new canes, it is sufficient to refer our readers to the illustration of a seedling cane grown at the Botanical Gardens, Georgetown, British Guiana. It yet remains to be proved whether the bulk of the seedling canes are richer to sugar, and are better adapted to the requirements of the planter than the old canes. A somewhat careful and protracted system of experiment and selection will have to be carried out in order to eliminate the worthless sorts, and retain only those of special promise. Already we understand that in one remarkable instance a seedling cane grown at British Guiana from a batch of seedlings raised at Barbados, has been pronounced to be superior to any of the existing canes. This is known as the Scard cane. No doubt many other equally promising sorts will be forthcoming in the future. In the meantime

FIG. 81.—A SEEDLING SUGAR-CANE. (SEE P. 528.)

we can only recommend those who have it in their power to improve so valuable and important a plant as the tropical Sugar-cane to persevere along the well-known lines followed in regard to other economic plants. They must be satisfied with small advances at a time, and patiently wait for the success which must wait upon all intelligent and well-directed effort.

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the Society will be held, as usual, in the Drill Hall, Westminster, on Tuesday next, November 1. At 3 o'clock in the afternoon a paper on "Fruit Trees in Pots" will be read by the Rev. W. WILKS, M.A., Secretary of the Society. Among the exhibits, Chrysanthemums will doubtless form a conspicuous item, especially as the Council have offered prizes for competition in three different classes. Growers wishing to enter the lists should communicate with the superintendent of the shows as to the space, &c., required.

CHISWICK GARDENS.—The Michaelmas Daisies, which for a long time past has been one of the chief floral features in the gardens of the Royal Horticultural Society at Chiswick, have now practically finished flowering for this year. Their place, however, has been filled by the large collection of Chrysanthemums, which have been moved into the large conservatory. The plants are in a fine healthy condition, and will soon be a mass of flower worth seeing during the approaching winter months.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.—Mr. GEORGE J. INGRAM, Secretary, 59, Parliament Street, London, S.W., desires us to inform intending Candidates for the next Election of Pensioners on the funds of this Institution, that they should at once apply for the necessary forms of application, which must be returned to him on or before November 25th next, after which date they cannot be received.

LINNEAN SOCIETY.—The first meeting of the session 1892-93 will be held on Thursday, November 3, 1892, at 8 P.M. precisely, when the following paper will be read:—"A Theoretical Origin of Endogams through an aquatic habit." By the Rev. Professor HENSLAW, M.A., F.L.S.

HORTICULTURAL INSTRUCTION.—The following course of lectures is in progress at the Heriot-Watt College, Edinburgh. The lecturer is JOHN H. WILSON, D.Sc., F.R.S.E., and the class meets on Fridays, 7.15 to 8.15 P.M., commencing Friday, October 14, 1892, and terminating March 17, 1893. The course of lectures has been instituted primarily with reference to the training of gardeners; it will, however, include throughout, instruction of interest to amateurs. Excursions to notable gardens and nurseries will be arranged during the session. The lines to be followed in the course are briefly indicated in the following syllabus:—

Good and bad soils: Their physical and chemical characters; the plants which grow on them naturally; weeds. Choice of site for a garden: The physiography of the garden; landscape gardening—its various schools. Land surveying: The application of geometry, mensuration, and levelling in the laying-out of grounds. Hothouses: Their design, construction, and uses; heating and ventilating. A flowering plant: Its structure and life history; conditions conducive to healthy growth. Natural and artificial renovation of the soil: Diseases of garden crops; methods of prevention and cure. Vegetables, fruits, and flowers: The history, uses, and peculiarities of varieties commonly grown. Culture of culinary vegetables: Growing for market. Culture of fruits: Pruning, thinning, and training. Culture of herbaceous and pot plants. Principles of propagation: Cutting, layers, and grafts; sports; the fertilisation of flowers; the reproduction of Ferns and Selaginellas; the "improvement" of plants by hybridisation and selection. A review of the progress of horticulture: A gardener's education; hor-

ticulture as a recreation; town gardens; school gardens.

The fee, 5s. per session; matriculation fee, 1s. Among other classes which gardeners may attend with great advantage are the following:—Freehand-drawing, geometrical-drawing, botany, agriculture, chemistry, geology, physiography, and elementary Latin.

— The first of a series of lectures and demonstrations on "How Plants Grow" was given on Friday evening, October 14, at Witham, Essex, by Mr. DAVID HOUSTON, F.L.S., staff teacher on biology to the Technical Instruction Committee (County Council). The great importance to dwellers in the country of an earnest and systematic study of the structure and physiology of plants was insisted upon, first as part of a liberal education, secondly as a hand and eye training, and thirdly as a help to the fuller understanding of the why and wherefore of plant growth, leading, perhaps, to suggestions of practical utility in everyday practice on the farm. The lecturer traced the wonderful transformations by which air and soil get converted into living plant structures, and ended by an appeal to his audience to approach the study of plants seriously, to work earnestly, and to pin their faith to practical work.

— On Saturday, October 15, Mr. T. D. FISH delivered a lecture at the Town Hall, Northampton, on the "National and Local Importance of Horticulture, with Practical Hints on Fruit Growing." The lecture was delivered under the auspices of the local horticultural society and of the Technical Instruction Committee of the County Council.

FRUIT CULTURE.—The Cambridgeshire County Council has arranged with Mr. T. D. FISH to deliver a series of lectures upon the above subject, one to be given each week for five weeks. Outline of the course: Introduction, "National and Local Importance of Fruit Culture."

The Apple.—Propagation by seeds, layers, cuttings, suckers, budding, grafting. Planting: the time, mode, distance, transplanting. Stocks: Crab, Doucin, Paradise, &c. Forms and sizes of trees: standards, dwarfs, pyramids, espaliers, &c. Pruning: summer, winter, root. General Culture: mulching, watering. Sub-cropping with grass, vegetables, flowers, bush fruit, and Strawberries. Best varieties for profit, kitchen and cooking, table, preserving, cider cottage gardens, special localities. The harvesting of Apples: gathering, storing, packing, sorting, marketing. Diseases of Apples: canker, mildew, mealy-bug, aphides, maggots, caterpillars, weevils, antidotes, cures.

The Plum.—History and importance of the Plum. Propagation by suckers, budding, grafting. Varieties: Gages, dessert, kitchen, Prunes, Damsons. Planting: time, distance, method. General cultivation: pruning, training. Gathering, packing, marketing, drying, and preserving. Prevention and cure of insect and other insects: blight, barrenness, canker, gum, red-spider, grub, aphides, saw-fly, white scale, beetles, ear-wigs, Lady-birds, weevils.

The Pear.—Improvement of the Pear: agents thereof, our first technical teachers in Pear culture. Varieties for particular purposes and places. Planting in orchards, in gardens, distance, time, mode. Propagation: the Quince and other stocks; double or multiple grafting for fertility. Cultivation, general and special. Marketing, packing, drying. Pests and diseases, their prevention and cure.

The Cherry.—Propagation: planting, pruning, training, cultivation. Leading varieties: Bigarreans, Geans, Dukes, Morellos. Pests and diseases, their prevention and cure.

Bush Fruits.—The Gooseberry: conditions of successful culture, propagation, planting, pruning, training, general and special culture, varieties for flavour and weight, green and ripe.—Currants: red, white, black, special pruning of black, best varieties. Pests and remedies.

The Raspberry.—Its propagation: by suckers, cuttings, seeds, time, mode, distance of planting, pruning, training, general culture, varieties, single and double bearing, uses.

The Strawberry.—Its history: uses, private and commercial importance, its propagation, planting, best soils and manures for, special culture in beds, rows, raised banks and pots, forcing the Strawberry, retarding ditto, varieties, early, mid-season, and late, distinct species.

Small trees and bushes will be exhibited in the lecture-room as object lessons in the arts of grafting, budding roots and tops, pruning, training, and planting. Questions will be freely welcomed and fully answered at the close of the lectures, which will last over an hour. Admission free. The course is designed so as to be useful to people with small gardens, as well as to large fruit growers.

GARDEN SEED CLUB.—A meeting of members of the Flower Show committee was, says the *Hampshire Index*, held at Broughton, Hants, lately, to consider the advisability of formulating some scheme to assist the working men of the village to purchase garden seeds and seed Potatoes, thereby promoting a better class of vegetables being grown. Mr. J. G. EDWARDS, Broughton House, presided, but there was only a small attendance of labourers. The chairman explained the proposed scheme, and after considerable discussion it was unanimously resolved to start a seed club. To every 1s. paid in by members, 3d. will be added by the committee.

HOOKE'S "ICONES PLANTARUM."—The September number contains illustrations of numerous newly-described plants, mostly of purely botanical interest, but some of interest to gardeners also, such as the tiny *Trichomanes Sayeri*, the two handsome *Clerodendrons* from Madagascar (*C. Baronianum* and *C. eucalycinum*), which would be well worth introducing. The *Hoyas* from the Solomon Islands, *H. Guppyi* and *H. affinis*, would also be desirable introductions. *Petrachondra Hamiltoni* is a very remarkable little plant, referred to *Borages*, but it has opposite glabrous leaves, no scales in the throat of the corolla, but plentiful perisperm.

BOTANICAL EXCHANGE CLUB.—The Report for 1891, printed by JAMES COLLINS & Co., Southgate, Manchester, is interesting even to those whose duties forbid them indulging in that eager search for specimens which formed the delight of their youth. Good work among Brambles, Roses, Hawkweed, and Willows seems to have been done, and some attempt made to discover the reason for their extreme variability. Unless this is done, the collection of all these minute variations is no more instructive, if so much so, than the accumulation of postage stamps. Among the plants mentioned are hybrids between *Senecio vulgaris* and *S. squalidus*, between *Linaria repens* and *L. vulgaris*, *Rumex crispus* and *R. obtusifolius*. Another curious plant is a form of *Urtica dioica*, nearly, but not quite, stingless. The male plant was in this amiable condition, not so the female. This is a very interesting observation in connection with the object of the formation of these hairs. It is obvious that those who desire to grasp their nettle should choose the var. *inermis*. The rarity of female plants of *Salix decipiens*, as compared with the males, is also noteworthy.

SOME INSECTS WHICH INFEST APPLE TREES.

When the gardener has put grease-bands round the stems of his trees to entrap the winter moth, and made his preparations for spraying the heads in early summer with London Purple, he is by no means sure that the leaves will not be eaten off by other insects, which have lain *perdus* in cocoons or webs all through the winter. These are mostly to be found in the twigs, and should be cut off with long-handled caterpillar (parrotbill) shears, or burnt by means of a paraffin lamp or an ordinary torch of tarred rope fastened on a slender pole. The following are the more common species:—*Porthesia chryso-rhœa*: the caterpillar has two red lines on the back, and white stripes on the sides. The young caterpillars, if abundant, will devour the whole of the foliage. *Aporia crataegi*: the caterpillar short, and thinly covered with hairs, ash-grey, on the back

black, with two broad orange-yellow or brown-red and one yellow stripe on the feet. *Vanessa poly-chloros*: the caterpillar is brownish-grey, with pale rusty-yellow back and side markings, and rusty-yellow thorns. They form in the early part of the year a nest, which is readily seen at a distance, and the caterpillars are as destructive as the former. All of these require that the trees get cleared of them before the leaves appear. We know of some large trees in a suburb of London which were for two years robbed of their foliage by one or other of these caterpillars, and at length the trees died. It was simply a case in which the proprietor did not know how to deal with the pests.

LOOK ON THIS PICTURE AND ON THAT:

LONDON. — Middle-aged Londoners can well remember the time when there was scarcely a tree to be seen planted in any thoroughfare of London or its suburbs. From an inquiry recently made in seventeen London districts, it has been found that three only are now absolutely treeless, while in the other fourteen the number of trees in the public highways is 14,700. Of these 5158 have been planted by the boards and vestries, and 5323 returned as planted by builders and others. Hampstead returns 2712, included in the first total, and adds, "Very small number planted at cost of vestry, and cannot state number planted by builders or property owners." Besides the expense of purchasing and planting, the average cost of maintenance is about 1s. 3½d. each tree per annum. In some instances, in the case of new streets, the trees have to be protected in the first instance with guards at the cost of the owners. In one district they are properly guarded and staked, and the cost included in the apportionments. In eight districts wooden guards are used, and in one expansion metal guards. In Hammersmith, trees are not allowed to be planted in streets of less width than 45 feet; and Streatham is restricted in this regard to not less than 40 feet street width.—*Daily News*.

PARIS. — In the parks and gardens of Paris there are not fewer than 299,294 shrubs and 22,038 trees; but these may be excluded from the comparison. Let us confine ourselves to the trees planted in the streets and roads. These are estimated by M. ANDRÉ at 100,000. As to the cost of an *arbre d'alignement*, that is set down as about 200 francs. This latter amount, even if we include preparation of the soil and maintenance, seems excessive; but so it is stated in the *Revue de l'Horticulture Belge* for the present month.

MASSACHUSETTS HORTICULTURAL SOCIETY.

—The first part of the *Transactions* for the year 1892 has been issued, and has more than local interest by reason of the excellent essays it contains. Among them we may note one on the soil and irrigation of Egypt, one on late experience with Insects, in which Professor RILEY says:—"The introduction of the cyclone nozzle, the discovery of the value of kerosene emulsion, the resin washes, and the hydrocyanic acid treatment, all of which have resulted from my work for the United States Government, together with the discovery of the Bordeaux Mixture as a fungicide, have virtually revolutionised our methods of dealing with insect diseases, so that the advance in the last few years is unprecedented in the history of horticulture. The first four discoveries are the results of scientific and experimental methods, while the Bordeaux Mixture was a chance discovery. The use of these five discoveries is now almost universal." That may be so in the States, but at our present rate of progress, it will be long before ignorance, routine, and prejudice will permit of a like statement to be made here with truth. Other subjects dealt with are the sewage question, road-making, fungous diseases and their remedies, by Professor HUMPHREY; the preservation of fruit, peat, &c. The account of the library of the Massachusetts Horticultural Society will be read with interest here.

MR. JOHN HORNE, F.L.S.—It is a matter of regret to record that Mr. JOHN HORNE, F.L.S., has been compelled, on account of ill-health, to resign

the post of Director of Gardens and Forests at Mauritius. Mr. HORNE has been connected with the Botanical Gardens at Mauritius for more than thirty years. He was trained at Kew, and his first appointment was as assistant gardener under the late Mr. JAMES DUNCAN, in 1861; he was appointed sub-director in 1866, and ultimately succeeded to the Directorship in 1877. Mr. HORNE had charge both of the Botanical Gardens and of the Forests in Mauritius for fifteen years, and he discharged the onerous duties of the dual posts with fidelity and success. The Mauritius Gardens, under his care, attained to a high degree of efficiency, and they were rendered of great service in promoting local indus-

of the inhabitants of Mauritius, and they have proved of signal service to the community by the introduction and distribution of new Sugar-canes and other plants of a valuable character. 'It is impossible to over-estimate the share taken by the Botanical Gardens in introducing hardy and productive varieties of Sugar-canes to Mauritius at a time when the Sugar industry was imperilled by the attacks of destructive insects and disease. Canes to the number of 130 varieties were introduced by the Gardens, propagated at them, and distributed from them, not in a cane or so of each variety, but in quantities of several thousand canes of each of the leading sorts to each planter.' Of late years the

Journal of the Bombay Natural History Society. In a letter announcing Mr. CARSTENSEN's death, he was described as popular and painstaking, and it was stated that he had greatly improved the garden under his charge, and he had contemplated extending the character and value of the collections so as to render them of greater scientific interest. *Kew Bulletin.*

COPPER COMPOUND AND THE POTATO DISEASE.—Owing to the increase of the Potato disease during the summer of 1890, A. GIRARD, who has a high reputation in Europe as a specialist in the chemistry of horticulture, thought it might be interesting to endeavour to find out whether the various

FIG. 82. AGED TONGUELEAF APPLE TREES. (SEE P. 528.)

tries in the island. Mr. HORNE afforded valuable help in the production of the *Flora of Mauritius and Seychelles*, by Mr. J. G. BAKER, F.R.S. (published in 1877), and he contributed the principal supply of specimens illustrating the flora of the Seychelles. In 1877, Mr. HORNE visited Fiji (at the instance of its Government), and wrote *A Year in Fiji* (published in 1881), a work dealing chiefly with the vegetable resources of the colony. In a letter addressed by Kew to the Colonial Office, dated March 15, 1888, the following testimony was borne to the late Director's services:—"Mr. HORNE has most ably and industriously carried out his duties at Mauritius. The Mauritius Gardens are deservedly one of the most popular institutions in the island. They are annually visited by more than one-third

Gardens have rendered additional services in endeavouring to alleviate local depression by carrying on inquiries with the view of establishing minor industries. Indeed, there would appear to be no function attached to the Mauritius Botanic Gardens which Mr. HORNE has not endeavoured to discharge as fully as the means at his disposal have allowed." *Kew Bulletin.*

MR. G. CARSTENSEN.—News has been received at Kew of the death from typhoid fever of Mr. G. CARSTENSEN, Superintendent of the Victoria Municipal Gardens, Bombay. Mr. CARSTENSEN was recommended for this post by Kew in 1886. He appears to have done excellent service in promoting horticultural matters in Bombay, and he has contributed several papers on gardening subjects to the

copper compounds which have been proposed for destroying the parasitic ailments of plants possessed any power of adhering to the leaves, and what consequent reliance might be placed upon them. To determine this, he carried out experiments last year, which consisted in submitting the plants to the action of "artificial rains," of calculated intensity and duration, having previously treated the leaves with various compounds of copper, such as those which are being "boomed" so much just now. He then submitted the leaves to chemical examination, determining by analysis the quantity of copper adhering to their surfaces both before and after their being washed by these rains. Three types of rain were adopted, namely, (1), a violent storm, rain corresponding to a fall of 17 mm. of water in twenty-two

minutes; (2), a steady downpour, giving a fall of 15 mm. in six hours; and (3), a gentle rain giving a fall of 10 mm. in twenty-four hours. The watering apparatus, by means of which these "artificial rains" were produced, consisted essentially of an inverted, somewhat flat, cone revolved at the rate of eight times per minute by a hydraulic motor, from which the water could issue uniformly in drops, from the lower surface. GIRARD's conclusions are given in a paper in the *Comptes Rendus*, cxiv. (1892), pp. 234-236, and are substantially as follows:—1, That the proposed copper compounds have very different powers of adherence to the leaves of plants. 2, That it is under the action of violent rains and mechanical disturbance that the deposited copper disappears. 3, That, among these copper compositions, that which gives way the most is the copper-lime wash; that a diminution in the proportion of the lime slightly increases the stability, and that the addition of aluminous (clayey) substances is of no practical use. 4, That the copper-soda and the verdigris washes adhere nearly twice as well as the copper-lime wash, and that, best of all, is the copper-lime-sugar wash which has been suggested by Mons. MICHEL PERRET. GERAUD is therefore of opinion that it is to these three last compositions that practical people who desire to preserve their Potatoes from the fungus should turn. [1 mm. = about 1-25th of an English inch.]

THE THAMES AS A SEED DISTRIBUTOR.—Dr. GUPPY has, in the *Journal of the Linnean Society*, an interesting paper in which he discusses the seeds, seed vessels, and other vegetable drift which this river is ever carrying to the sea, especially in autumn, winter, and spring. January and February have yielded the largest collections. Dr. GUPPY used a tow net opposite the weirs and in the eddies, afterwards picking out the seeds, buds, insects, eggs, &c., which the rubbish contained. The seeds were in many cases sown so that the germinating properties could be tested, and the life-history of many of the water plants elucidated. In this way the effects of ice, of sea water, and other conditions on the duration of vitality of seed were studied. The absence of certain plants from the drift is as remarkable as the presence of others. Seeds of Pondweeds (*Potamogetons*), of the yellow and white Water Lily, *Persicaria*, Water Buttercup, Forget-me-Not, and *Scirpus lacustris*, it appears, have little or no power of floating, but remain in the river mud. Nevertheless, some of these plants, e.g., *Scirpus lacustris* and various *Potamogetons*, are found all over the globe, whence Dr. GUPPY considers that they are disseminated by the agency of birds.

GHEENT QUINQUENNIAL.—This is the object of a report published for one halfpenny by the Foreign Office, as one of a series of "subjects of general and commercial interest." It is pleasant to see our Government alive to the importance of these meetings, but the Report contains nothing that has not been already published, and the schedule has been distributed among our horticulturists for some time.

CHINESE FLORA.—Mr. HEMSLEY describes in the last-issued part of the *Journal of the Linnean Society* various newly-discovered plants from central and western China. Mr. PRATT's collections (which are those principally dealt with) were made in the neighbourhood of Tachienlu, near the frontiers of Tibet, at an elevation of about 8350 feet. The flora of the mountains of western China, says Mr. HEMSLEY, abounds in showy herbaceous plants, equally, if not surpassing, the richest districts of the Himalayan region, of which, indeed, it is a continuation. As in the eastern Himalayas, every valley has its peculiar species.

BRANCHED PALMS.—In the last part of the *Journal of the Linnean Society* is an article by Mr. D. MORRIS, on "The Phenomena Concerned in the production of Forked and Branched Palms." This branching has, so far, only been observed in about ten genera, and it is due either to the destruction of a terminal bud by insects: or in other cases to the inordinate development of a lateral bud, which

thus assumes dimensions equal to those of the terminal bud, or to the replacement of flowering shoots by leaf-buds.

BAMBOO STAKES.—The use of Bamboo for Hop-poles, stakes, &c., is suggested, by reason of their cheapness and durability, and there is no doubt that, for certain purposes, they would advantageously replace Larch and various coppice woods. But it must not be forgotten that the hollow canes form excellent shelter for predatory insects, and therefore their use for growing plants is not altogether desirable, unless the end be plugged. We have lately seen some *Chrysanthemums* mangled by some unseen enemy, but on splitting open the Bamboo-sticks, both earwigs and woodlice were found to have taken refuge therein.

A DENDROLOGICAL SOCIETY.—A Society for the study and utilisation of trees and shrubs has been instituted in Germany. Botanists, gardeners, foresters, and amateurs, interested in trees are invited to join. The first general meeting will be held in the spring of 1893, at a place to be hereafter noted. The President is HOFMARSCHALL VON ST. PAUL, the Vice-Presidents Prof. DIPPEL, Darmstadt; Prof. ENGLER, Berlin; Dr. Pfützer, Heidelberg; the Treasurer, HERA BEISSNER, Inspector of the Botanic Garden, Bonn.

STOCKTON PUBLIC PARK.—The busy town of Stockton-on-Tees is to be provided with a park for the recreation of the inhabitants—a gift of Major ROPNER, and after whom it will be named; and on Thursday, October 20, the first trees were planted by Mrs. ROPNER and Mrs. HIND.

BLACK RICE OF BURMAH.—In the last number of the *Kew Bulletin* Professor CHURCH gives the details of an analysis of a black-grained Rice which becomes glutinous when cooked. The pigment is identical with that which gives the purple colour to Grapes, the leaves of the Copper Beech, and many other plants. The Rice contained 9.2 per cent. of albuminoids and 2.2 per cent. of oil, as contrasted with an average of 7.3 per cent. and 0.6 per cent., respectively, in other varieties. "Chemical analysis amply confirms the high dietic value assigned to black Rice by native opinion."

AMERICAN AND CANADIAN APPLES.—The total number of barrels of Apples imported into Great Britain last season was 1,450,000.

BOURNEMOUTH AND DISTRICT GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.—At the fortnightly meeting of the above, on Wednesday, the 19th inst., Mr. A. SKINNER, of Highcliffe, near Christchurch, read a comprehensive and valuable paper on "The Composition, Uses, and Abuses of Farmyard Manure." With reference to the comparative merits, from a manurial point of view, of the various materials used as litter, Mr. SKINNER expressed himself strongly in favour of straw. He deprecated the use of peat-moss litter, notwithstanding the fact that its analysis showed a higher percentage of nitrogen than that contained in straw. It is interesting to note that in the discussion which followed, peat-moss manure was condemned by a large majority of the speakers. Possibly the light, peaty nature of the soil in the district may account for this. It would be instructive to learn the experience of those who have applied it to heavy clay soils.

THE WORLD'S FAIR AT CHICAGO.—In order that bee-keeping in Great Britain shall be represented at the World's Fair at Chicago in 1893, the British Bee-Keepers' Association is endeavouring to get up a large exhibit of this year's honey worthy of the mother country, to send over. For this purpose bee-keepers throughout the kingdom are invited to send donations of bottles of extracted honey, in quantities of 5 lb. or upwards, to the Association, who will undertake to forward them free of cost to the exhibition. The only proviso required is, that the name of the locality in which the honey was gathered must be given, and the name of the donor

will appear on his exhibit. All communications of bee-keepers wishing to contribute, should be addressed to the Secretary, British Bee-Keepers' Association, 17, King William Street, Strand, W.C.

CULTIVATION OF GAMBIE IN BRITISH NORTH BORNEO.—The well-known tanning substance known as Gambier, the produce of *Uncaria Gambir*, which has attracted some attention of late, owing to the high price it has been realising in the European markets, and in consequence of which the cultivation of the plant has been recommended in other countries than the Straits Settlements, seems to promise well in North Borneo. In a report on "The Trade of the Territory administered by the British North Borneo Company," recently issued from the Foreign Office, the writer says:—"Gambier, whose growth is entirely confined to this part of the world, is now being tried, the Government having started a small experimental garden at the back of Sandarkan. The plants at the end of the year were four months old, and as large as those in the Straits Settlements at six months. This promise continues at the time of writing, and the Chinese in charge say they will be able to commence boiling two or three months earlier than in Singapore."

THE "GARDEN" PLATES.—In the *Garden* for October 15 is an alphabetical list of the coloured drawings that have been published in the *Garden* up to the end of 1891. This is a list for which workers ought to be thankful.

"REICHENBACHIA."—The first volume of the *Reichenbachia* (second series) is dedicated by special permission to the Empress of Russia.

CHRYSANTHEMUM EXHIBITING.—A grave discussion has lately been held as to the size of the boards on which Japanese *Chrysanthemums* should be exhibited, and ultimately it was agreed that a board (a specimen of which was exhibited decorated with flowers) should be adopted as a standard and of the following dimensions:—28 inches in length, 21 inches in width, 7 inches from centre to centre of each hole, 8 inches in depth at the back, and 3 inches in front. It is as lamentable as it is strange that the only point discussed was the dimensions of the board. Why should beautiful flowers be exhibited in the ugliest manner possible. It certainly is not necessary for purposes of study and comparison.

AN ACT OF VANDALISM.—We are sorry to hear that the magnificent Sabal Blackburniana, which was for years so fine a feature of the Ghent Botanic Garden, has been cut down. Its destruction was says the *Bulletin d'Arboriculture*, consequent upon that of the old dilapidated glass-houses, which have now been replaced by smaller and strictly utilitarian buildings. Much regret and considerable indignation has been roused by this act of vandalism, for the Palm was considered the finest of its kind in Europe, its measurements being computed as follows:—Height, 55 feet 8 inches; fronds, more than 6½ feet across, with petioles over 9 feet long. The case in which it was growing had been frequently lowered, so that its demolition was no easy task. We are sure that English botanists will join their Belgian *confrères* in regretting the loss of this splendid specimen; many visitors to Ghent next spring will miss it and its fellows from their accustomed places.

MEMORIAL TREES.—During his stay at Euston Lodge (says the *Stock Exchange*), the Prince of WALES planted a specimen of *Ginkgo adiantifolia* on the lawn at Stone Hall, one of the most ancient structures on the Euston estate. In this romantic spot a flower garden has been laid out under the personal direction of Lady BROOKE, who terms it her "Friendship Garden," her friends and relatives being invited to plant trees, evergreens, &c., there as mementos of their visits to the Lodge. Lady BROOKE is also arranging a Shakespearean border, the object being to include in it every plant mentioned in SHAKESPEARE'S works.

PACKING FLOWERS.—Our old correspondent, Mr. J. SHEPPARD, gardener at Woolverstone Park,

Ipswich, gives in a communication received from him some time since, a hint about sending flowers to a distance in deal boxes, and that is to soak the box well in water, and let it drain for an hour, before putting in the flowers, Fern fronds, and other foliage. The reason for so doing is to prevent the flowers and foliage parting with their moisture, as they assuredly will do if the wood of which the box is made is very dry when they are packed.

ORCHID NOTES AND GLEANINGS.

DENDROBIUM PHALANOPSIS (*Fitzgerald*), "BISTERNE" VARIETY.

THERE is now in flower in the fine collection of John Mills, Esq., of Bisterne, Ringwood, a very beautiful and distinct form of *Dendrobium Phalenopsis*. The flowers are large, well-formed, and of excellent shape.

FIG. 83.—FOXWHELP APPLE. (SEE P. 528.)

Boxes so treated, especially in the summer time, remain moist for a length of time, and their contents are kept fresh longer than would otherwise be the case. Mr. SHEPPARD does not like tin boxes, as the interior rapidly cools, or it gets heated if a glimmer of sunshine touches it.

PLANT PORTRAITS.

CERCIS SILIQUASTRUM, *Garden*, October 15.

COSMOS SPECTABILIS, *Revue Horticole*, August 16.

fruit of a purplish-bronzy tint, ripening late. Described by M. Carrière in *Revue Horticole*, October 15.

PAPAVER GLAUCCUM, *Revue Horticole*, October 15.

PEACH, HALES' EARLY, *Canadian Horticulturist*, October.

RHODODENDRON RACEMOSUM, *Garden*, October 8.

TILLANDSIA DURATHI, *Revue Horticole*, October 1.

TRADESCANTIA SUPERBA, Linden and Rodigas, *Illustration Horticole*, t. 155.

ZYGOPETALUM CRINITUM, *Garden*, August 13.

The distinction, however, lies in this remarkable peculiarity—that every flower on each spray has pure white sepals; the petals are deep purple, and the lip a still darker purple, producing a very charming effect. I saw hundreds of plants of *Dendrobium Phalenopsis* in flower recently at Messrs. Sanders of St. Albans, and at Mr. Cypher's, Cheltenham, of every shade between white and purple, but there was not one so remarkably distinct as this. Mr. Mills has also in flower a good white form, but the most perfect white variety that I have seen is now in flower at Mr. Cypher's. *Emeric S. Berkeley.*

CYPRIPEDIUM CASTLEANUM X.

Reichenbachia, ser. 2, t. 45; see *Gardeners' Chronicle*, December 13, 1890, p. 702. A hybrid raised by Mr. Maynard in the establishment of Sander & Co., from *C. hirsutissimum* by *C. superbienis*, and quite intermediate in character. The flower has a bluish-purple tint. The dorsal sepal is darker in colour than might have been anticipated. The petals are much flatter than in the mother plant. The lip and staminode closely resemble those of *C. superbienis*.

ODONTOGLOSSUM CERVANTESII VAR. DECORUM.

Reichenbachia, ser. 2, t. 46.—A fine and rare variety of a charming little *Odontoglossum*. Tens of thousands of trees, principally Oaks, have within the last twenty years been felled, and hundreds of thousands of plants [Orchids] destroyed. This is mainly due, we are told, to the extension of railways in Mexico. It succeeds well in the *Odontoglossum*-house near the glass. In its native state, its pseudobulbs are every night bathed in moisture, which is usually dried up by the sun or wind of the morning.

CATTLEYA AMETHYSTOGLOSSA.

Reichenbachia, ser. 2, t. 47. For this, relying on the conditions under which it is found in Nature, the following treatment is counselled—a high temperature when growing, with as much light as possible without scorching, and an abundance of water, with a decided season of rest after the growths are completed.

CATTLEYA X ARNOLDIANA.

Reichenbachia, ser. 2, t. 48. A splendid hybrid, raised in the establishment of Messrs. Sander & Co. from *Laelia purpurata* by pollen of *Cattleya labiata*.

ANGULOA UNIFLORA VAR. EBURNEA.

Flower uniform, ivory-white, without any spots.

BULBOPHYLLUM DEAREI.

originally described in our columns, 1883, pt. 2, p. 108, f. 17, as *Sarcopodium Dearei*. Flowers yellow, with reddish-brown transverse veins, lateral sepals stained purple; petals light yellow, veined with brown; lip creamy-white, spotted with purple, so delicately balanced that it moves with a touch. *Lindenia*, t. 345.

CATTLEYA ACKLANDIÆ.

Perianth segments green, blotched with purple; lip 3-lobed, lateral lobes folding over the column, front lobe flat, pinkish-violet. Native of Brazil. *Lindenia*, t. 346.

LELIO-CATTLEYA ELEGANS.

now considered to be a natural hybrid between *L. purpurata* and *Cattleya Leopoldi*. It is a native of South Brazil. Sepals and petals beautiful rose-purple, lip intense glowing crimson, except the lower half of the tube, which is sulphur-white, veined with light purple. *Lindenia*, t. 347.

HOME CORRESPONDENCE.

ROTATIONS OF CROPS.—The necessity and importance of a change of crops is generally admitted, and farmers at one time were bound down by their leases to hard-and-fast rules of rotation, and yet we all know that cottagers and allotment-holders go on from year to year and from age to age growing Potatoes on the same plot or piece of ground, and still get good yields, when that scourge, the *Peronospora*, does not seriously affect the tops, and cause the tubers to be small or to rot. Not only has it been proved that Potatoes will go on and do well for an indefinite period without change of soil, but we have it recorded by Mr. Cobbett that a barrister friend of his has grown Peas on the same border for over half a century, and states that if at any time the crop had been finer than of late, it must have been something extraordinary, as the haulm was as full of pods as any he had ever seen in England. We know that the cottager does not and cannot change his soil, but the barrister may have done so, and gone afar for fresh, or renewed it from time to time, as it is generally supposed that Peas soon tire of the same

land; but why they should do so, or be more exhaustive than Potatoes, that root and feed so greedily, as some of the strong-growing commoner kinds are prone to, only chemical analysis can tell us, for we must first know what minerals plants take out of the earth before we become aware or decide what it is necessary to put back previous to sowing or planting again. Scientists tell us—and there can be no doubt, I think, but there is much truth in what they state—that plants derive a good deal of their nourishment through the leaves from the air, and convey certain chemicals to the soil in which the roots are, where the mineral matter is held in Nature's larder for future use; and if it were not for this wise provision, a large portion of this part of the globe would ere now have been barren. For all this, we gardeners and most tillers of the soil believe greatly in muck or manure, and the stronger it is the better we like it. Would that we could get more of it, as most of us have such demands for everything, that we have to crop, crop, crop; and almost before one is off another is in, and so we go on year after year. Although the land is never idle, it does get change, and in and through that we manage to go on; but to pursue a regular rotation or system is, with most of us, out of the question. The beneficial effect, however, in face of the Potatoes and Peas, cannot be overrated, and I strongly advocate and advise the rotation of crops, or to give as much change to the land as can be managed, for what one kind of vegetable leaves another makes use of, and prepares the way for the next, and the ground is more free from insects. *J. Sheppard.*

TRAFALGAR PARK.—During an interesting stroll through the well-wooded grounds and pretty flower garden at Trafalgar Park, Salisbury, some weeks ago, I noticed that a narrow border having a row of tuberous-rooted *Begonias* in the centre, with a row of Golden Pyrethrum on either side, followed by two rows of blue *Lobelia*—one on each side next the grass verge—had a quiet, but, at the same time, a telling effect. It was also noticed that the silvery-leaved *Centaurea ragusina*, planted alongside of dark-foliaged plants in a border running parallel with the west front of the mansion, showed to great advantage. This plant for some reason is not met with so often as it deserves to be; it is of easy culture. Offsets inserted singly in small pots, will soon emit roots, and will form good plants by bedding-out time next year. The preparation of the pots should be as follows:—Place a few potsherds in the bottom, and cover with a bit of moss or a few half-rotted leaves, for drainage, and fill with three-parts of light loamy soil, one of sweet leaf-mould, with a surfacing of silver-sand; then place them in a cool pit, near the glass, in which a somewhat dry atmosphere is obtained, I may be permitted to remark that the flower garden at Trafalgar is opposite the west front of the house, and runs with a rapid descent towards the River Avon. It is geometrically laid out, and has an ornamental fountain in its centre. Owing to the very elevated position of Trafalgar House and grounds, grand views of local and distant scenery, comprising hill and dale, wood and water, are obtained therefrom. These extend on the south and south-west to Kingwood, Wimborne, and other towns of more or less importance in Wiltshire and Dorset. The landscape on the west, which extends to the north, is a charming one, and embraces several miles of the Avon valley, with its rich water meadows and beautifully-wooded slopes, nestling amongst which are the village of Alderbury and Alderbury House, the residence of G. Fort, Esq. Westward thence, on the banks of the broad clear running Avon, are Longford Castle, with its towers and minarets, and the spire of Salisbury Cathedral, &c. *H. W. W.*

WINTER CUCUMBERS.—At one time these were thought a good deal of, and every effort and care used to be bestowed in the growing of them, and as few places had the proper convenience for their cultivation, gardeners had to give the closest attention, and exercise a good deal of skill to produce them. With the modern low and light houses with close-fitting lights, or fixed roofs, that are now so much in use, the matter is not so difficult, as the sun's rays are fully admitted, and with ample means of heating, Cucumbers are obtainable the whole year. The narrow span-house, running north and south, should be provided with a path down the middle, and a bed, 2 feet 6 inches in width, on each side, fitted with slate bottoms, resting on or just above the pipes, of which there should not be less than three, and to afford top-heat six others, two along close to each wall, and one on

either side of the pathway resting on the curb, as then a high and suitable temperature can be maintained without any trouble. To be successful, a start should be made with strong plants, which may either be raised from cuttings or seed, the first-mentioned being preferred by some, as they are considered to be the more fruitful. Another point that has to be taken into account is the variety grown, as much depends on that, for it does not follow that a Cucumber that is suitable for summer culture, and is a good free-cropper then, is equally adapted for winter. Many have been recommended for the latter purpose, and I think I have tried most or all of them, but as yet I have found none that is in any way equal to the old Lord Kenyon's, which not only has a hardy constitution, but it is a prolific bearer, the fruit tender, and about 10 inches long, and excellent flavour. A market gardener to whom I recommended it, told me that he would not be without it on any account, his customers not being satisfied with other varieties, and his fruits make good prices. Gardeners and others, then, who cultivate Cucumbers should, therefore, make a note of this, and try Lord Kenyon's in their next batch, and if they do I venture to predict it will be their chief favourite. In preparing the bed for the plants, a layer of rough material should be placed over the slates, and on that a thinly-cut turf, grass side downwards, and then a ridge laid along the middle of mixed soil, consisting chiefly of roughly-chopped fibry loam, and equal quantities of peat, if it can be easily obtained, or leaf-mould, as Cucumbers delight in such decaying vegetable matter. A fair distance to plant is from 3 feet to 4 feet apart, and the stems should be run up and tied under the trellis, so as to allow for any subsidence or settlement of the bed, and prevent root straining and hanging. As soon as the main shoots get near the top of the house they should be stopped, and all laterals treated the same, one joint above the fruits, and when the plants get thick a general thinning out will be necessary, so as to give room for fresh growth and foliage. This growth may be accelerated by top-dressing, but only a little of this should be put on at a time, and none should be added before the roots appear on the surface, and when it is needful to afford water, weak and tepid liquid manure may sometimes be applied, and no water should be applied that is not of the same temperature as the bed. The proper temperature to keep winter Cucumbers is from 65° to 70° by night, and from 10° to 15° higher by day, with plenty of atmospheric moisture, according to the state of the weather, syringing and damping the pipes and floor when there is a bright clear sky during early morn or eve, and refraining when conditions are the reverse. Air should be sparingly supplied, and only during sunshine. *J. Sheppard.*

OPENING OF KEW GARDENS.—Following up your remarks in last week's *Gardeners' Chronicle*, I would suggest that some of us who think with you, should ask for an opportunity to urge our views on the First Commissioner of Works. This seems all the more necessary, since I understand the First Commissioner is about to receive a deputation on the other side. Any of your readers who feel inclined to join me, will communicate with me, I will do my best to start the matter.—*M. Foster, Sec. R.S., Great Shelford, Cambridge, October 25, 1892.*

BIG ELM AT TRAFALGAR PARK.—In reply to Mr. Hurst's inquiry, the large Elm tree, stated in the *Gardeners' Chronicle* of the 15th inst. as standing close to the chapel and opposite to the kitchen garden as measuring 24 feet round at bottom, measures, at 7½ feet high, 20 feet 6 inches. A large Elm trunk is to be found on Havering Green, Romford, Essex, but it is much decayed. *G. F.*

A BRAVE OLD ELM.—It is only the Oak which so far seems to have found a place in the annals of song, but the Elm is one of the noblest trees that we have, considering that we so largely employ the latter for the making of coffins, and the former was once our chief material for the construction of ships, it is small matter for surprise that poets should have sung of the "brave old Oak," and have ignored the Elm. Not long since a paragraph ran through the press mentioning the destruction by fire in the Home Park, Hampton Court, of a very old Elm tree. Believing what was said to be true, I was very much surprised to see this veteran the other day certainly in some respect damaged, but still in wondrously robust health. The age of this remarkable tree must of necessity be speculative, but it may be anywhere from 500 to 1000 years. The bole is so

hollow, that within it forms an area of some 10 feet in diameter, and the existing structure is but a wall of bark, perhaps 10 inches thick. So far it is pretty solid, as there is no large hole through which it is possible to pass to the interior. There are perhaps larger hollow boles, but this one certainly is a remarkable one. The fire, which no doubt was in some way accidentally caused, scorched the inner wall of the shell, and materially burned the huge dead branch that still stands, also the leafage on the young growths of the head in the centre was destroyed, but that all round the margin remains green, and no doubt the other branches will break green again next year. Thus the veteran, a monument of vegetative dignity remains. How many of these wondrously large old veterans there are about the country, and the exact age and dimensions of which it would be interesting to learn. It is a pity they could not as long as possible be specially preserved, as are now ancient but human monuments. *A. D.*

HIPPEASTRUMS FOR GREENHOUSE CULTURE.

—Frequently as is the culture of this class of showy flowering bulbs discussed, rarely, if at all, is reference made as to their adaptability to greenhouse culture. As far as my observation extends, they are all classed as stove plants in trade catalogues. Certainly, I have not Messrs. Paul & Son's list to refer to; I cannot, therefore, include them in my remarks. Judging by what I saw at Messrs. Paul & Sons, High Beach Nursery, they treat these plants during the summer months on cooler methods, and if they have made successful advances under this system it would be well if they gave publicity to it. I refer to them because they are successful cultivators, and the raisers of some meritorious novelties in Hippeastrums. I need not say how desirable it is, from a trade point of view, the public should be better informed on such a subject. As there are certain species or varieties which will succeed and bloom well in the ordinary greenhouse, the names should be given under the heading of "Greenhouse Plants," to say the least. By this means something would be done to remove the popular impression that Hippeastrums (Amaryllids) are exclusively warm house exotics. It is to be regretted, moreover, that so little has been done to increase the hardier varieties, and that the efforts of hybridists have been exclusively devoted to the tenderer species. Forty years ago, when I had the care of the then best collection of Hippeastrums in this country, that owned by Messrs. Garraway & May, when H. Ackermani was the parent of nearly all the finest large-blooming varieties, which were then very popular, and to be counted by scores, the feeling was the same as it too generally is to-day. "They were exotics, and required stove heat to insure successful culture." A limited number of varieties had succeeded in the greenhouse, and to such I now refer, and hope others may be able to extend the list of these. These comprise Hippeastrum (Amaryllis) Johnsoni, H. Johnsoni hybrida, H. vittatum, and, no doubt, H. pardinum, of Peruvian origin. This being so, why may they not be made seed-bearing parents of a race of equally hardy varieties. As a matter of fact, too little care is taken of these varieties or species, as the case may be. As regards starting them to grow as early in the spring as possible, whereby the season's growth may be so advanced in the early summer as to insure each being well ripened before autumn and winter. A collateral consideration associated herewith is the judicious drying-off necessary in connection with the latter phase. This must not be done too hurriedly, though, on the arrival of bad weather, it cannot be maintained too strictly definite until the season for growth returns. *William Earley*, [Spencer, when gardener at Bowood, used to grow his Hippeastrums in frames in bottom-heat so as to get them matured at an early part of the year when he wanted them in bloom in the autumn and early winter. He was enabled by the employment of bottom-heat to get an early and a late bloom on the same plants within the year, of course, affording them a rest after each flowering period. *Ed.*]

ROSA INDICA SANGUINEA.—There are few small-growing Roses that can be successfully compared with the old Crimson China; its neat shining green leaves, and its small and very double crimson flowers, which are produced abundantly, give to it a distinctness which marks it of exceptional value either for growing in pots for the decoration of the conservatory, or for planting in beds and masses on lawns. Its habit of growth is dwarf, thereby giving to it an additional value as a suitable plant for an edging to

beds in which taller growing Roses are planted. No particular cultivation is required, for under ordinary treatment and in warm soil it will thrive and flower freely. Very little pruning is necessary, and this should be carried out at the end of the month of March by removing small and weak shoots from the centre of the plants, and shortening the stronger shoots by half their length. *H.*

CHRYSANTHEMUM JOTTINGS.

THE PARKS.—The season during which our autumn favourite reigns supreme in the world of flowers is again upon us, and we heartily welcome the commendable shows that are to be seen in the parks, &c., of the London County Council. That their efforts are appreciated the authorities have continual testimony from the crowds of interested admirers that throng the houses set apart for their accommodation at all times when it is possible for general business people to indulge in a little recreation. Of course, it is upon Saturday afternoons and Sundays that the majority endeavour to satisfy their floricultural aspirations, and during these times, it is difficult to obtain such an acquaintance with the flowers that one would like. It is therefore advisable, if possible, to see them during any other part of the week, when the peculiarities of each variety can be noticed and admired. Generally, the plants this year are about ten days later than usual, but the collection at Finsbury Park is a decided exception to this. In the matter of grouping, very little advance has been made, and although, as at present arranged, these banks of bloom (as various as they are many) are exceedingly bright, still there is no rest for the eye, and not half the pleasure can be derived from such an arrangement as would result from the grouping of varieties according to colour. There should be sufficient of one colour together for the eye to rest upon, and then the various groups of colour so arranged that striking contrasts or pleasing harmonies could be obtained. Stereotyped banks are again the rule, but at Southwark Park—if the colours have not been studied as they should have been—the grouping of the plants shows more tasteful arrangement than does the collection at any other of the parks we visited.

FINSBURY PARK.

This fine park in the northern part of the metropolis, formerly under the management of the late Mr. Cochrane, has long been famed for its show of Chrysanthemums, and although Mr. Melville, from Dulwich Park, has not long succeeded to the management, the display this year again holds its own with any one of the others. As usual, the plants are accommodated in a large span-roofed house some 100 feet long, and about 18 to 20 feet wide. The plants form a centre group facing to each side, and the path extends all round immediately next the sides of the building. Here are a good number of incurved varieties, some of which are now carrying good blooms. The general forwardness of the collection as compared with others has already been remarked upon. Japanese forms are numerous. Altogether, there are some 3000 plants in at least 200 varieties. Many of these are very late sorts, and are not yet placed in the exhibition-house. The large Etoile de Lyon was here in very good form—if one excuses a little want of colour—some of the blooms are at least 12 inches across, and of a corresponding depth. Madame John Laing was also noticeable as a very pretty-coloured Japanese. Louis Buchner had some fine buds, that promise well, but at present they are not expanded. Edouard Audiguier is still an attractive variety, the beautiful velvety appearance of the petals being very distinct. There are some good blooms of the rather loose-looking Sunflower, and Stanstead White was eliciting much admiration from the persons visiting the display. Amongst the incurved varieties deserving of notice were George Glenny and the Golden George Glenny, Lord Alcester, Prince of Wales, and M. R. Bahuant—this latter is a very fine bloom. Some pretty blooms of the yellow Mons. Charles Lebossez would appeal strongly to lovers of

the Anemone group; and a new variety that has not yet made its reputation, called Delaware, has ray petals of a straw colour, whilst the florets are of primrose-yellow. At present its appearance is rather flat, but it may yet turn out a good thing. The show has already been opened three weeks, and it may be expected to be at its very best in about a week. The park is not far from the station of the same name, but a tram can be taken from the station to the upper gates, close to which is the house where the display is exhibited.

BATTERSEA PARK.

Take train to Battersea Park station on the London and Brighton railway, and a short walk will bring you to the large span-roofed house in the reserve garden, that has been set apart for the accommodation of the Chrysanthemums. The plants are arranged in a single bank along the house, which is about 12 feet wide, and over 100 feet long. There are something like 2000 plants in about 250 varieties, but at present only a very small proportion of them are in bloom; indeed, the collection will not be at its best until another fortnight. The general appearance of the show is good, and the foliage and blooms are fresh and promising, bearing testimony to the care that has been given to them by those who have been responsible for their culture. Some remarkably good blooms of Avalanches cannot fail to elicit praise from all, especially those that favour the florists' flowers, for in this variety the petals are placed naturally so evenly, that its general appearance is almost as formal as a Camellia. Eynsford White, a good white flower of slightly more loose habit, was also in very good form at this place. The new sport from the White Madame Lecroix, named Mr. C. E. Shea, was in bloom, but not specially good; its colour is yellow, and it is quite possible that another year it may prove to be a good thing. Florence Davis, the new Japanese, will be certain to take with many people, on account of its peculiar appearance. The flower is very loose, and is quite green until fully expanded, when it becomes white. Many new varieties seem to be got together at Battersea, and some good promising buds were to be seen, on Mr. J. S. Dibben, a variety which is also but little known. Another new one called Mr. A. H. Neve, is a pink Japanese, but the blooms here were not yet developed, and it was impossible to judge of its merits. William Tricker, on the other hand, had some fine blooms, of a rosy-pink colour, shaded with white, and the habit is dwarf and very good. The number of visitors to Battersea is enormous, and it will be worth while to any interested in these exhibitions to make an excursion into this thickly populated district and compare it with the other displays elsewhere.

SOUTHWARK PARK.

This park is classed as of third-rate importance, but the show of Chrysanthemums to be seen here this year cannot in any sense be described as a third-rate exhibition, indeed, a very fine collection has been exhibited to the public, and one cannot but regret that the authorities have not more accommodation in which they might show the result of their time and attention to better advantage. However, the very best has been made of the available means, and if any who have been to the other parks and seen the general similarity in the arrangement of the plants deign to visit Southwark, they are sure to be pleased with the effect produced here. Perhaps in some of the other places there is not the same incentive to less common grouping, for here the house that is available is something like 25 feet wide, and this admits of centre and side groupings. The groups on the sides are wavy and artistic, while the plants in the centre are grouped into two pyramids, one at either end, gradually falling to its lowest point in the centre of the house. The house, however, is altogether unable to meet the requirements of the case, and a tent has been erected, where the remainder of the plants have been accommodated—if one can use such a term, for the

dark position that they have to occupy here is the reverse of accommodation, and good blooms are not looked for from these. However, for the present, and until the late varieties commence to bloom, the effect, perhaps, is heightened by the addition of this tent, which has been erected and furnished in form something like a corridor, and opens out into the house in which the other, and more fortunate, plants are blooming. The whole collection is very late, and will not be at its best until nearly three weeks. A few days ago there were good blooms of Madame Lecroix, Louis Bœhmer, Oriental, Prince of Wales, and the delightfully pretty Pompon Mdle. Elise Dordan. There are about 3000 plants, and include a wonderful variety, the general excellence of which reflect high credit upon Mr. Bailey and his grower. Next year we hope to congratulate Mr. Bailey upon the better accommodation that is now promised. Southwark Park is close to the Deptford Road Station of the East London Railway, and is situated in the midst of a teeming population, to which such a sight as a Chrysanthemum show must be delightfully refreshing.

THE INNER TEMPLE.

Again the benches of the Inner Temple have opened their annual display of Chrysanthemums gratuitously to the public. This was the very first of its kind that was opened in the metropolis, and the exhibitions that are now so much appreciated in various parts of this great and populated area are, no doubt, due, in some measure, to the initiative taken by the authorities at the Temple. During the last two years better accommodation has been provided, and the plants are now, as they were last year, grouped together in two small lean-to houses, which are fairly well adapted to such a purpose. The best of the blooms to be seen a few days ago were M. R. Bahuant, William Holmes, Bismarck, Ulrich Brunner, and Comte de Germiny. This is the most central of any of these displays, but like most "forerunners" it has been the means of promoting such zeal as has resulted in exhibitions now greatly superior to the original one.

(To be continued.)

THE ROSERY.

OUR OLD-FASHIONED ROSES.

At the great exhibition at Wolverhampton in July last, on the third day, special prizes were offered for twenty-four distinct varieties of garden decorative Roses, to be shown in bunches; and for twelve varieties also, and some excellent exhibits were staged, especially by Messrs. Cooling & Sons, Bath, and Mr. Coombs, gr. to the Earl of Dudley, at Hilmley. I regarded these exhibits with intense interest, recalling so forcibly the memories of half a century since, when the old Rose du Roi (The Crimson Perpetual), was almost our only autumnal Rose of any merit, and this Rose we almost always had in bloom out-of-doors in December on the south coast. Not only were these exhibits at Wolverhampton regarded by me with interest, for ladies seemed especially to appreciate them and freely make notes, for these old kinds staged in nice clusters were a revelation of the past to a great many. The old H. C. Fulgens, Noisette Lamarque, N. Jaune Desprez, Aimée Vibert—still unbeaten in its class, some of the old Ayrshires and Sempervirens, and others were to be seen.

My object in penning these few lines is to ask societies where Roses are encouraged to bring into more prominence exhibits of our old-fashioned Roses in bunches, and as an old hand in floriculture with getting on for sixty years' experience, I should greatly like again to see some blooms of the old Rose du Roi. I well remember the introduction of our earliest H.P.'s, and when Madame Laffay first bloomed, the interest this fine old variety created. I well remember the great old pioneers of Rose culture, Adam Paul of Cheshunt, William Wood of Mansfield, Thomas Rivers of Sawbridgeworth, and Lane of Berkhamstead, and Mr. Wood was a wonderful raconteur of what Othello called "hair-breadth

'scapes," during his travels in the secret service of those days. One had only to listen, no need to talk, for he possessed a great fund of anecdotes and adventures. The Rose work of the fathers descended to worthy sons, and the late Mr. George Paul and Mr. William Paul, the latter happily still spared to us, continued the good work, the latter by his most valuable little treatise on Rose culture, published so many years since. Mr. Charles Wood succeeded his father, and so at Sawbridgeworth and Berkhamstead the work has been kept going by the sons. May it long continue so, at the original home of the Roses, and at Waltham and Cheshunt especially, our old affectionately remembered Roses can be seen in the summer months; but it is at our provincial exhibitions especially, I should like to see them again. My memory goes back to the days when the hybrid Chinas and hybrid Bourbons were the rage, grand old Brennus, Blairii No. 2, Fulgens, Beauty of Billiard, Coupe de Hébé—grand old Rose, Chénédolle, Paul Ricaut and others, were such a phalanx of beauty. Ah! many are now almost forgotten and things of the past, as so many of their cultivators in those days are also. D.

CLASSIFICATION OF ROSES.

This is a subject upon which many different opinions exist, and one which is very puzzling to the majority of growers. Some simple method of classifying Roses is wanted, and this must be something by which the different sections or classes can be readily distinguished. At present I do not see how it is at all possible for one to say whether some Roses are a Tea-scented, Noisette, or a hybrid Tea, and in some few cases it would seem to possess equal claims to the hybrid perpetual section.

Several new Roses that were exhibited this season come under the head of these doubtful ones. We find the majority of catalogues giving the following classes, viz., hybrid perpetuals, Tea-scented, Noisettes, Chinas, and Bourbons. While others go further, and divide them into hybrid Teas, hybrid Chinas, and hybrid Bourbons, to say nothing of additional small classes like the Polyantha, Boursault, Banksian, Scotch, Macartney, Moss, Provence, and others. All of these sections are doubtless correct, and are probably simple enough to some. But that they are not so to the majority, and that there is even much confusion among our largest growers, is fully borne out by a casual glance at their various published catalogues. Take Messrs. Paul & Son, B. R. Cant, F. Cant, G. Prince, Keynes & Co., Cranston & Co., with many others of our most prominent growers, and you will find them at variance about some of our best-known Roses. We can scarcely wonder, therefore, if the average amateur forms the opinion that the thing is overdone, or at any rate very much mixed up. I will endeavour to give a few examples of my meaning. Viscountess Folkestone was sent out by Mr. Bennett as being a hybrid Tea; but before I go any further into the subject, I will explain that there is confusion as to what constitutes a hybrid Tea Rose. Some class Cheshunt hybrid among the hybrid Teas, because it is the result of a cross between Madame de Tartas (Tea) and Prince Camille de Rohan (hybrid perpetual). Lady Mary Fitzwilliam may be named as another well-known Rose, that is almost always classed as a hybrid Tea. This grand variety resulted from crossing Devonians (Tea) with Victor Verdier (hybrid perpetual). Now, to my mind, these are not true hybrid Teas, such being a cross between two varieties of Tea Roses. Kaiserin Friedrich is my idea of a hybrid Tea. This was a cross between Gloire de Dijon and Perle des Jardins. Returning to Viscountess Folkestone, we find that Mr. B. R. Cant calls it a hybrid perpetual, while Mr. F. Cant places it among them, but initials it as a hybrid Tea. Among the best growers in the country we have this Rose classed as a Tea, a hybrid perpetual, and as a hybrid Tea. Which is correct?

The National Rose Society have decided that these so-called hybrid Teas are to be exhibited among the hybrid perpetuals, and this has doubtless

induced many to class them as such. Mr. F. Cant's plan of placing them among the hybrid perpetuals, and initialing them as hybrid Teas, is a good idea, as far as a catalogue is concerned, but it does not get rid of the difficulty. La France is recognised as a Hybrid Perpetual; then why is Augustine Guinoisseau called a hybrid Tea? Yet it is so in many catalogues that one would naturally look upon as authorities upon Roses, notwithstanding this variety was simply a sport from La France, and in no way a hybrid between this and any other Rose.

Turning to the Tea-scented and Noisette Roses, we still find a considerable amount of confusion. My impression has always been that a Noisette Rose had the very distinctive character of blooming in trusses; take Aimée Vibert and William Allen Richardson for examples. But then, do not Madame de Watteville, Madame Cosin, Madame de Tartas and others, bloom in trusses? We have both dwarf and extra strong growers among the Teas proper, and among the Noisettes; we also find Maréchal Niel as often classed among one as the other. How, then, is one to distinguish a Noisette from a Tea-scented Rose? Both have the same characteristics in growth, floriferousness, and scent. Where, too, lies the difference between some of the Polyantha Roses and the smaller of the Noisettes? But I will not go deeper into the matter, or my paper will become confusing in itself. One should not find fault with existing arrangements unless they see a way to improve them. Now, I would suggest that all of the Tea-scented and Noisette Roses be classed together, and that the true hybrid Teas (i.e., those crossed between two Teas or Noisettes) be placed with them. Then I would put the classes known as hybrid perpetuals, the so-called hybrid Teas, hybrid Bourbons, hybrid Chinas, &c., into one common class, and designate them "Hybrids of Roses." At present it is somewhat difficult to find a Rose in a large catalogue, unless one knows to what section it belongs; even then, as I have already shown, there is no knowing which class it may be in.

I should very much like to see the National Rose Society take this matter up, or else publish some guide to the classification of Roses. Surely the queen of flowers should not be left in this unsatisfactory state, so that one does not know which of three classes a Rose belongs to. A. Piper, Uckfield.

SOCIETIES.

ROYAL HORTICULTURAL Scientific Committee.

OCTOBER 18.—Present:—Dr. M. T. Masters, in the chair; Mr. Morris, Mr. Blandford, Professor Church, Dr. Scott, Rev. W. Wilks, Dr. Müller, Dr. Russell, Rev. G. Henslow, Hon. Sec.; and Mr. J. Carruthers, visitor.

Bouillie bordelaise.—A communication was received by Mr. Blandford from Mr. E. D. Till, The Priory, Eynsford, Kent, stating that of twenty-six experiments in gardens, fields, and allotments, on different sorts of Potatoes this season, they were all completely successful. The mixture used consisted of 1 lb. of copper sulphate, 1 lb. of freshly-slaked lime, 1 lb. of syrup, and 5 gallons of water. The following are some of the more striking results selected from Mr. Till's report:—"Early Puritan, once, twice, and thrice syringed respectively—all were good, the haulm being green four weeks after the others had decayed. When not syringed, 25 per cent. were bad. Wilford Park, considered a good disease-resister; of seven rows not syringed, 5 per cent. only were bad. Of a row twice syringed all were good, cleaner, and of a more regular size than the others. Of Sutton's Abundance, 20 to 25 per cent.; Victory, 20 per cent.; and Chancellor, 3 per cent. were bad when not syringed. Reading Giant, when twice syringed, were all good, with more than a fourth excess of crop; all being cleaner and of a more regular size than in the rest of the field, where it gave an average crop. The haulm was green to September 25, six weeks after the others had decayed. Of seven varieties grown on allotments, of Snowdrop twice

syringed, all were good; once syringed, eight tubers, bad; not syringed, sixteen bad. Of Early Puritan, twice syringed, twenty-five tubers bad; about sixty being bad on two adjacent rows not syringed. In a garden, Beauty of Hebron, once syringed, all were good and very clean; while of two rows not syringed, 30 per cent. were bad." Mr. Till concludes his report with the following general remarks:—"The leaves were very thoroughly syringed on both surfaces, and at a date (July 1, 15, or 20 to 23) when growth had nearly attained its full development. The quantity applied at the rate of about 350 gallons per acre. The most striking results were on the early sorts. The later sorts were freer from the disease. The Reading Giant plot showed a largely increased quantity in comparison with the adjoining rows, while the superior size, regularity, and quality were very marked. Also the Ware, or selling sizes, were very much more regular. This was no doubt due to the haulm being kept in vigour for five to six weeks after the rest of the haulm in the field had withered. There is no mistake about the great advantage of the solution when applied to this variety; improved growth was not so marked in other sorts, though certainly very noticeable generally." Professor Church remarked that the use of the syrup was to make the hydrated oxide of copper more adhesive to the leaves, and he observed that dextrine had been used in conjunction with sulphuretted mixtures for Roses and Chrysanthemums; but the special value of sugar was, that it entered into combination with the lime, and was subsequently set free, retaining all its adhesive properties. Mr. Blandford added that the use of sugar had been adopted as the best result from a large series of experiments carried out in France.

Docks Attacked by Grubs.—Dr. Masters received a communication from Perthshire, together with specimens of grubs which had attacked some Docks. As Rhubarb was about to be placed on the same ground, being of the same family (Polygonaceae), it was thought the latter might be attacked also. It proved to be the Ghost Swift, *Hepialus humuli*; but, as Mr. Blandford observed, this insect is so very generally distributed that no remedy could be suggested other than the destroying the plants with the grubs as much as possible.

Walnuts Imperfect.—Mr. Noble sent specimens of Walnuts, in which the shell was imperfectly developed in certain places, though the kernels appeared to be sound. It was suggested that the cause might be defective root-action from a clay soil, or perhaps the sharp frost in June, when they were very young.

Fog Report.—Some discussion arose as to the desirability of recommending observations on the injuries to plants by fog during the coming winter, and pursuing them in a systematic way. It is proposed, therefore, to reconsider the programme drawn up in 1891 at the next meeting of the Scientific Committee, especially in its bearings on the best practical methods of resisting the injuries of fogs in the construction or adaptation of plant-houses or otherwise.

Peat wood.—Dr. Russell showed some specimens of wood from a peat bed of a few feet in thickness on Dartmoor, in Devonshire, where there are no trees at the present time. One was that of Birch, but the other was not recognisable on inspection. It was referred to Kew for comparison with some museum specimens.

Fasciated Holly.—Mr. G. Paul sent boughs of Ilex Donningtonensis with this peculiarity. It appears to be a variety particularly liable to fasciation. The cause of fasciation is still unknown among trees. It is particularly common in the Ash and Cotoneaster.

Canonia capensis.—Flowering sprays of this shrub were sent by Mr. Burbidge. He observes that it is an old plant, but not often to be seen in gardens at the present time.

Pelargonium Sport.—A new double variety was received from Mr. Cannell called Double New Life, having the peculiarity of the petals being white, red, and flaked in the same blossom. It originated from a double Vesuvius called Wonderful. A flaked variety of the single Vesuvius appeared in the Isle of Wight in 1888. It has also sported to a salmon colour, as well as white, several times. The leaves are peculiar, in having acquired almost a purple tint. The original Vesuvius was raised by Messrs. A. and F. Smith, of Dulwich, in 1868.

Egyptian Figs.—Mr. Henslow exhibited an instrument used in Egypt for cutting off the tops of the nearly ripe fruit of the Sycamore Fig. It consists of a circular strip of iron, one edge being sharpened, and inserted like a loop at the end of a stick. The

object is to allow the insects to escape (*Sycophaga crassipes*, Westw.), which always infest that species. The Sycamore is never propagated by seeds in Egypt. The custom is apparently very ancient, and the Hebrew word translated "cultivator" as applied to the prophet Amos (ch. vii., 14) really signifies "scraper," as correctly given in the Septuagint version (written at Alexandria). It is described by Theophrastus and Pliny, but no mention is made of the insects. As the fruit becomes sweeter, it was thought to ripen them.

NATIONAL CHRYSANTHEMUM.

OCTOBER 24.—A largely-attended meeting of the General Committee of the above took place on this date at Anderson's Hotel, Fleet Street, E.C., at 7 P.M., R. Ballantine, Esq., in the chair. Some correspondence was read between the Rev. J. Bird, the President of the Loughborough Chrysanthemum and Fruit Society, as to an application for affiliation, Mr. Bird affirming that it was sent in by a person no longer officially connected with the Society, and that the application was made on behalf of a bogus Society to mislead the Committee. It appeared the affiliation fee had been paid by the applicant, and the usual documents and passes sent to him. It was resolved that the Secretary be instructed to return the amount of the affiliation fee to the sender; and that the Loughborough Society be affiliated if the committee so desire it. Resolutions were passed: 1. To the Dowager Duchess of Sutherland, expressing the great regret of the President and committee at the loss of one of their Vice-Presidents—the late Duke of Sutherland; and presenting to the Dowager Duchess the expression of their sympathy and condolence. 2. To the present Duke of Sutherland to the same effect, and expressing the hope Her Grace's name might still be retained among the list of Vice-Presidents. On the recommendation of the Floral Committee, the Secretary was instructed to forward to Mr. John Earland, Wellington, New Zealand, the Silver-gilt Medal of the Society, in recognition of his enterprise in sending the frozen blooms of Chrysanthemums to this country. A proposition that Silver and Bronze Medals be placed at the disposal of the Floral Committee, with a view of encouraging the production of groups and collections of plants and flowers at the meetings of the Floral Committee, was referred to the schedule sub-committee. Also the resolution in favour of the enlargement of show boards for Japanese blooms, passed at the recent Conference. The following were appointed a schedule sub-committee for the revision of the schedule for 1893, Messrs. Addison, Bevan, Boyce, Crane, Davis, Gordon, Gibson, Fowler, Jones, Stevens, Wynne, and the officers of the Society. Resolutions were passed that the members of the Floral Committee be invited to the judges' luncheon on November 8; that the annual dinner take place at the end of October or early in November, and a smoking concert in January. The Secretary reported that the President, Sir Edwin, accompanied by Lady Saunders, would attend at the Royal Aquarium on November 8, and take part in an opening ceremonial. The Chairman called attention to a paragraph which appeared in the last issue of the *Journal of Horticulture*, containing what the paragraph termed a "serious allegation" against a member of the Floral Committee, which he thought ought to engage the attention of the committee. After some discussion, the officers of the Society were requested to form a sub-committee to investigate the charges, and take such steps in relation thereto as they might think desirable. Seventeen new members were elected, including one Fellow. The Chairman was heartily thanked at the close of a long sitting.

ENQUIRY.

"He that questioneth much shall learn much."—Bacon.

KINDLY inform me what artificial maoures I can use now to top-dress a bed of Noble Strawberry, which I wish to be very early, and to have large individual berries. The bed is on a sheltered, sunny slope, and can be watered. It got a large dressing of bone-meal and sulphate of potash before planting last April, but no farmyard manure. The plants are 1 foot apart in the rows, and 2 feet between each row. Is there any danger of watering and manuring now at this hindering the earliness? *New Subscriber.*

SEEDS.

LONDON: Oct. 25.—Messrs. John Shaw & Sons, Seed Merchants, of Great Maze Pond, Borough, London, S.E., report a scanty attendance on to-day's market. Clover seeds have this week assumed a more quiet aspect. As regards Winter Vetches, the demand has during the last few days, much improved, and the supplies being exhausted, full prices are realised. The new Koenigsburg Tares being cheap, and good, attract attention. Haricots and Peas are steady with an improving tendency. For both white and brown Mustard seed there is a strong inquiry at advancing rates. Canary seed is firm, but without much movement of stocks. Hempseed is getting dearer. Linseed, Buckwheat, Bari, and Millet realise full prices. Rape-seed keeps very cheap.

FRUITS AND VEGETABLES.

SPITALFIELDS: Oct. 25.—Quotations:—Brussels Sprouts, 1s. 6d. to 2s. per half-sieve; Spinach, 1s. 6d. to 2s. per bushel; Savoys, 2s. 6d. to 4s. 6d.; Cabbages, 4s. to 6s.; Collards, 2s. 6d. to 4s.; Cauliflowers, 3s. to 7s. per tally; Sea-kale, 8d. to 1s. per punnet; Greens, 1s. 3d. to 1s. 9d.; Turnips, 1s. 6d. to 2s. 3d.; Carrots, 1s. 6d. to 2s. 6d.; Onions, 2s. 9d. to 3s. 6d.; Parsley, 1s. 6d. to 2s. per dozen bunches; Horseradish, 1s. to 1s. 2d.; Celery, 6d. to 1s. per bundle; Cucumbers, frame, 2s. 6d. to 3s.; Leeks, 2s. 6d. to 3s.; Cabbage Lettuces, 4d. to 8d. per dozen; Cos Lettuce, 6d. to 1s. per score; Mustard and Cress, 1s. 6d. to 2s. per dozen baskets; English Onions, 5s. 6d. to 6s. per cwt.; Belgian and Dutch Onions, 5s. to 5s. 6d. per bag of 110 lb.; Spanish do., 6s. 6d. to 7s. per case; Carrots, 40s. to 50s. per ton; Apples, English, 2s. 6d. to 5s. 6d. per bushel; American do., 9s. to 10s. per barrel; Quinces, 2s. to 3s. 3d.; Tomatos, foreign 1s. to 1s. 6d. per box; Peas, 3s. to 4s. per half-sieve.

BOROUGH: Oct. 25.—Quotations:—Cabbages, 3s. to 4s. Marrows, 3s. 6d. to 4s. per tally; Cauliflowers, 1s. to 1s. 9d. per dozen; Brussels Sprouts, 1s. 6d. to 2s. per half-sieve; Lettuces, 6d. to 1s. per score; Carrots, 2s. 6d.; Turnips, 1s. 6d.; Parsley, 1s. 6d. per dozen bunches; English Onions, 4s. 6d. to 6s. per cwt.; Horseradish, 2s. to 2s. 3d.; foreign do., 1s. 6d. per bundle; English Apples, 2s. 6d. to 10s. per bushel.

FARRINGTON: Oct. 27.—Quotations:—Apples, 3s. 6d. to 4s. 6d.; Marie Louise Pears, 4s. 6d. to 5s. 6d. per bushel; Onions, Spanish, 6s. 6d. per case; English do., 130s. per ton; Parsnips, 3s. 6d. per bag; Turnips, 2s. 6d. do.; Celery, 12s. per dozen rolls; Cauliflowers, 5s. to 6s. per tally; Carrots, bag, 55s. to 60s. per ton.

POTATOS.

SPITALFIELDS: Oct. 25.—Quotations:—Main Crop, 60s. to 70s.; Snowdrops, 60s. to 70s.; Reading Wonder, 60s. to 65s.; Sutton's Abundance, 60s. to 65s.; Imperators, 50s. to 60s.; Magnums, 45s. to 60s.; Hebrons, 50s. to 65s. per ton.

BOROUGH: Oct. 25.—Quotations:—English Magnums, 40s. to 60s.; Hebrons, 40s. to 60s.; Snowdrops, 50s. to 65s. per ton.

FARRINGTON: Oct. 27.—Red Beauties, 65s. to 70s. per ton; white do., 65s. to 70s.; Magnums, 60s. to 65s.; Imperators, 55s. to 60s. per ton.

GENERAL AVERAGES: Oct. 26.—Hebrons, 40s. to 75s.; Magnums, 40s. to 65s.; Snowdrops, 50s. to 70s.; Imperators, 50s. to 60s. per ton.

HAY.

Averages.—The following are the averages of the prices at the metropolitan markets during the past week:—Clover, prime, 80s. to 115s.; do., inferior, 46s. to 75s.; Hay, best, 60s. to 110s.; do., inferior, 26s. to 50s.; and Straw, 26s. to 41s. per load.

THE WEATHER.

[By the term "accumulated temperature" is meant the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named; and this combined result is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

DISTRICTS.	TEMPERATURE.				RAINFALL.	BRIGHT SUN.
	ACCUMULATED.					
	Above (+) or below (-) the Mean for the week ending October 22.	Above 42° for the Week.	Below 42° for the Week.	Above 42° difference from Mean since Jan. 3, 1892.

The districts indicated by number in the first column are the following:—

0, Scotland, N. Principal Wheat-producing Districts—1, Scotland, E.; 2, England, N.E.; 3, England, E.; 4, Midland Counties; 5, England, S.

Principal Grazing, &c., Districts—6, Scotland, W.; 7, England, N.W.; 8, England, S.W.; 9, Ireland, N.; 10, Ireland, S.; (* Channel Islands.)

THE PAST WEEK.

The following summary record of the weather for the week ending October 22, is furnished from the Meteorological Office:—

"The weather, though still rather showery and unsettled, was much brighter over the Kingdom generally than for some weeks past; in the north-eastern parts of the country, however, considerable falls of rain, hail, or snow, were experienced.

"The temperature was much below the mean, the deficit ranging from 5° to 7°. The highest of the maxima, which were recorded on very irregular dates, varied from 57° in 'England, S.W.,' and 55° in the 'Midland Counties,' 'England, S.,' and the 'Channel Islands,' to 51° in 'Scotland, N.' and 'England, N.E.' On some days the thermometer scarcely rose above 40° in the north, and did not reach 50° even in the south. The absolute minima were registered as a rule, during the middle part of the week, and were unusually low for the time of year. In 'England, S.W.' (at Llandovery) the sheltered thermometer fell to 20°, and in nearly all other districts to between 24° and 30°; in 'England, E.,' however, the lowest reading was 31°, and in the Channel Islands, 38°.

"The rainfall considerably exceeded the mean in 'England, N.E.,' and slightly in 'England, E.,' in

all other districts there was a deficit; the fall over the southern parts of Ireland and England being especially slight.

"The bright sunshine was fairly prevalent, and exceeded the mean in almost all districts; the percentage of the possible duration ranged from 23 in 'Scotland, E.,' and 24 in 'Scotland, N.,' to between 34 and 44 in most other districts; while in 'Ireland, S.,' the percentage was 52, and in 'England, S.W.,' 55."

NOTICES TO CORRESPONDENTS.

* PHOTOGRAPHS, DRAWINGS, OR SPECIMENS.—We shall be pleased to receive from our Correspondents notes relating to interesting Gardens, together with Specimens or Illustrations of interesting Plants. Although circumstances prevent us in all cases from reproducing them, we are nevertheless glad to receive them, and as far as possible to utilise them for the benefit of our readers.

ASPARAGUS FORCING: *Young Gardener*. To obtain good results, lift the roots as soon as the growths are quite ripe; do this carefully, and lay them in fairly dry soil under cover for one week. Have ready a pit or frame, which has been filled with the fallen leaves of Oak or Beech, and which have been heated and turned over once or twice; and when the heat is at 80°, and declining, tread the surface level, and let it not be more than 1 foot from the glass. Then place a layer 4 inches thick of warmed leaf-mould over the leaves, pack the Asparagus roots close together—say forty to fifty in a batch—and cover and fill in tightly around them with leaf-mould; afford a thorough watering with water at 85° to 90°; put on the lights, but leaving a half-inch opening under each. The top-heat must not exceed 50°, either day or night, till the roots start, when the range may be 55° by night, and 60° to 65° by day. This must be regulated by means of hot-water pipes or douglings, if it be a frame or unheated brick pit. Cover the frames at night, and do not let the soil get dry. Keep a plunging thermometer or test-stick in the bed, and if the warmth rise above 80°, as it may do if the leaves were wet when put together, or the weather is mild, probe the bed where the most heat is found; this will let it out. When the shoots are up above-ground, air must be given daily, when weather permits, and all the light possible; therefore keep the glass very clear. Attention to these two points will secure good-flavoured "grass." Asparagus for soups only may be driven with a bottom-heat of 90°.

BOOKS: *Mushroom*. *Mushrooms for the Million*, by John Wright (published at 171, Fleet Street, E.C.).—*W. G. The Live Stock of the Farm*, by J. C. Morton (Bradbury, Agnew, & Co., 9, Bouverie Street, London, E.C.).—*HONDURAS: F. G.* There is no separate flora of the country, but you should procure Mr. Morris' little work on *British Honduras*.

CATASETUM: *J. B. Stone*. Send the whole inflorescence, the flower sent not being sufficient for identification.

COPPER SPRAY FOR MILDEW: *A. asks*, is spraying with copper likely to be injurious to the consumer? To which, on the authority of Dr. Pammel, in *Bulletin No. 17*, Iowa, Agricultural Station, we answer—yes, there would be danger if the consumer ate more than from 300 lb. of Grapes a day!

DRY ROT: *A. P.* A fungus, *Merulius lachrymans*. You will do better to remove the boards and burn them. Creasote, corrosive sublimate, carbolic acid, copper sulphate in the form of spray, might any of them be useful.

INSECTS: *A. P.* *Abies Nordmanniana* smothered with the Coccus which is so injurious to the tree. We fear that no remedy short of destruction by fire is likely to be of any service. Petroleum emulsion might answer if the tree is a small one.

MIXTURE TO KILL GARDEN PEST: *Ajar*. Don't, if you wish to keep out of the law courts.

MOISTURE ON THE WINDOW PANES OF FLORIST'S SHOP: *Gaucho*. Arrange some kind of outlet for the air of the shop near the ceiling, and an inlet near the ground level, and if a small stove or hot-water apparatus could be made use of, the steamy appearance would be avoided.

NAMES OF FRUITS: *Hartsdown*. 1, Cellini; 2, Catahead; 3, New Hawthornden; 4, Beauty of Kent; 5, not recognised.—*Ridley*. 1, Grenadier; 2,

Nonsuch; 3, Sops in Wine.—*North Devon*. 1, Cockle's Pippin; 2, Blenheim Orange; 3, Grenadier; 4, Carlisle Codlin; 5, Lane's Prince Albert; 6, not recognised.—*A. Dagg*. White Doynenné.—*W. A. Emperor Alexander*. *T. J. & Sons*. Rymer.—*D. McDonald*. 1, New Northern Greening; 2, Scarlet Nonpareil; 3, not known.—*C. W. E.* 1, Keswick Codlin; 2, Lord Suffield; 3, Cox's Orange Pippin; 4, Mère de Ménage; 5, King of the Pippins; 6, Marie Louise (Pear).—*Rob Roy*. 1, not recognised; 2, Royal Somerset; 3, Scorpion; 4, not recognised; 5, New Hawthornden; 6, Cox's Orange Pippin; 7, Warner's King; 8, Egg or White Paradise; 9 and 11, Minchall Crah; 10, not recognised.

NAMES OF PLANTS: *J. W.* *Ficus edulia* (Cooperi), native of New Caledonia.—*P. & Sons*. *Ficus* sps. You might kindly send a plant to Kew for comparison.—*A. B.* 1, *Alonsoa incisifolia*; 2, *Lycyesteria formosa*.—*Harris*. 1, *Davallia tenuifolia*; 2, *Adiantum concinnum latum*; 3, *Nephrolepis Duffii*; 5, *Selaginella viticulosae*; 6, *Cissus nantarctica*.—*W. B. I.* *Cypridium Ashburtonianum* ×; 2, *C. Harrisianum*.—*Jim*. 1, *Gesneria macrantha*; 2, *Dracæna pulcherrima*; 3, send better specimen with flowers; 4, *Fittonia Pearcei*.—*E. D. L.* 1, *Asparagus decumbens*; 2, *Sedum carneum variegatum*; 3, *Bambusa Fortunei variegata*; 4, *Pachyphyton bracteosum*; 5, *Davallia fijiense*; 6, *Gymnogramma tartarea*.—*F.* 1, *Helianthus rigidus*; 2, *Artemisia dioica*; 3, *Ajuga reptans variegata*; 4, Send in flower; 5, *Aster bessarabicus*.—*C. H.* 1, *Davallia bullata*; 2, *Adiantum hispidulum*; 3, *Pteris tremula*; 4, *Nephrodium molle*; 5, *Pteris argyrea*.—*C. L.* 1, *Cattleya Warcewiczii*; 2, *Oncidium excavatum* (aurosum); 3, *Cypridium longifolium*.—*J. M.* 1, *Aspidium cyrtomium falcatum*; 12, *Gymnogramma ochracea*; 19, *Adiantum hispidulum*; 44, *Davallia Tyermanii*; 7, *D. canariensis*; 71, *Asplenium baccidum*; 9, *Polypodium pustulatum*.—*J. K.* *Euonymus europæus*.—*Without Name*. 1, *Tamarix gallica*; 2, *Berberis Darwini*; 3, *Arbutus uva ursi*; 4, *Phyllirea angustifolia*; 5, not recognised; 6, *Diplopappus chrysophylla*; 7, *Xanthoxylon spinosum*.

ONCIDIUM CRISPUM: *E. M. C.* Your plant is kept too cool, it would do better if placed in the Cattleya-house, or where the temperature is kept at night for the approaching winter at 60° by night, and 70° by day. It is right to grow them on blocks as you are doing. Do not let it get dry.

ORCHIDS: *C. T. H. W.* Hybrids, a cross between two species. As regards your second question, it is a matter of opinion; we think you are right. In the third you are right; they are wrong.

PRESERVING BULBS FROM THE RAVAGES OF WIREWORM: *Chelsa*. When planting the bulbs, surround them with silver-sand, and sprinkle some soot over that. Bury Carrots, by making holes with a dibber, and pushing them into these just below the surface, amongst your planted bulbs. If the tops be cut off with a slice of the root they will not grow, and they will serve as a food for the wire-worm more to their liking than bulbs. Planting Parsley, Lettuces, or Radise, would have the same effect, but these plants would be unsightly in your bulb beds.

PROPAGATION: *Brown*. *Cistus*, rock Rose. Seeds or cuttings. The seeds should be sown in pans of light sandy soil in the spring, and kept under a hand-glass or in a cold frame till germinated. Cuttings may be made at the present season, and struck cool under glass; also in spring in slight bottom heat. In the former case the wood should be firm, and the length from 3 to 4 inches, in the latter the plants may be excited into growth in March, and soft growing tips taken as cuttings. *Chimonanthus*: by layering at this season.—*Coprosma*: easiest by layering.

THOMAS GREEN & SON, LTD.,

LEEDS and LONDON,

HORTICULTURAL ENGINEERS to HER MAJESTY THE QUEEN, call Special Attention to their Patent Wrought-iron Municipal or Angular Chambered and Tubular

HOT-WATER BOILERS,

And others with SHELVES, and HOLLOW or ORDINARY CAST-IRON GRATE BARS.

SADDLE BOILERS, With WATERWAY BACKS and WELDED BOILERS, any of which are specially adapted for Heating Greenhouses, Conservatories, Churches, Chapels, Schools, Public Buildings, Entrance Halls, Warehouses, Workshops, &c. They are the neatest, cheapest, most effective, and durable of any extant. The MUNICIPAL and TUBULAR ones are remarkable for their great heating power, slow combustion, and the length of time the fire will burn without requiring attention.

These Patterns secured the **FIRST and HIGHEST PRIZE—a SILVER MEDAL**—at the Royal Horticultural Society's Exhibition, South Kensington, London, June 1, 1881.

MUNICIPAL PATTERN BOILER, THE BEST EXTANT.

TESTIMONIALS.

Re HEATING APPARATUS. Borough Engineer's Office, Municipal Buildings, Leeds, January 9, 1886.
MESRS. THOS. GREEN AND SON, LTD., NORTH STREET, LEEDS.
 GENTLEMEN,—I have great pleasure in bearing testimony to the efficiency and satisfactory working of the Hot-water Heating Apparatus you erected in these public buildings.
 The buildings are four storeys high, and we have a total length of about 28,000 feet of piping in them, varying in size from 1½ in. to 6 in. diameter, with their connections, &c. The several offices and rooms can all be in operation at one time or separately, and the heat regulated by means of the valves to the temperature required, even in the coldest weather.
 Two of your Patent Municipal Pattern Boilers, No. 4, work the whole of this piping easily, although we have three of them fixed. They are very powerful and economical in the consumption of fuel, and I am pleased to be able to report of them and the apparatus so favourably.
 I am, Gentlemen, yours truly,
THOS. HEWSON, Borough Engineer.

Morley House, Bagot, St. Saviour's, Jersey, November 10th, 1886.
 GENTLEMEN,—The large Municipal Boiler which you sent me last year is doing its work satisfactorily; it is heating 5000 feet of 4-inch pipe in one of my vineries, and I am quite sure that it has power to work a much greater length, while in cost of fuel it compares favourably with my other Boilers.
 I have now five of your Boilers in use, and I cannot speak too well of their heating powers, or their comparatively small consumption of fuel.

MESRS. THOS. GREEN AND SON, LTD., LEEDS.
 Yours faithfully, (Signed) **G. W. BASHFORD.**
And HUNDREDS OF OTHER REFERENCES CAN BE GIVEN IF REQUIRED.

D A H F O D I L
 COUNTESS OF ANNESLEY.
 Splendid large cultivated Bulbs, to produce two and three flowers each, free by post, at 6s. 6d. per dozen.

THE CHEAP WOOD COMPANY,
72, BISHOPSGATE STREET WITHIN, LONDON, E.C.

FIXED.

From Mr. J. WILLARD, Head Gardener to the BARONESS BURDETT-COUTTS, Holly Lodge Gardens, Highgate, N., July 12, 1892.— "Dear Sirs, Having given your Improved Garden Gully a fair trial, I may say that it proves in use all that you claim for it, and in my opinion has, for the sides of walks and drives, many advantages over the ordinary grating. Perhaps the best proof I can give you of this is that, as opportunity offers, I intend to use them instead of gratings. Faithfully yours, J. WILLARD."—To Messrs. VINCE & VINE.
From W. WALTON, Esq., Secretary to the LONDON CEMETERY COMPANY, The London Cemetery Company, 29, New Bridge Street, Blackfriars, E.C., July 25, 1892.— "To Messrs. Vince & Vine, Highgate, I am very happy to testify that your Patent Gully-Frames in lieu of the old-fashioned gratings answer admirably. They were by my authority fixed in a new pathway made in Highgate Cemetery, and in the recent thunder showers they were severely tested and were

**THE IMPROVED GARDEN GULLY
(VINCE'S PATENT).**

This useful invention is a great improvement on the ordinary Garden Grating, and is especially suitable for billy walks and drives. As they never get stopped by rubbish or sand they effectually prevent the washing away of the gravel in heavy storms, and they save half the labour in cleaning out the cess-pools. The prices are:—

6-in., 1s. 6d.; 8-in., 2s.; 10-in., 3s.; 12-in., 6s. 6d.; 15-in., 8s.
(The larger sizes are very strong for carriage drives.)

Full Particulars on application. Testimonials:—

most effectual in preventing the scouring of the gravel. At the inspection my Directors were much pleased with them, and gave instructions that they were to be used when required at Nunhead Cemetery.—I am, yours truly, W. WALTON, Secretary."

From Messrs. CUTBUSH AND SON, Highgate and Barnet Nurseries.— "Highgate Nurseries, London, July 27, 1892.—Dear Sirs,—Referring to the Improved Garden Gully you fixed for us some months ago, we are glad to say it answers admirably. As you are aware, our Nurseries here are very billy, and during the recent storms all the ordinary gullies were blocked, whereas yours was in good working order. We shall not hesitate to recommend the same to anyone requiring the gullies for sides of paths and carriage-drives, and we feel certain, when it is known, there will be a great demand.—We are, yours faithfully, WM. CUTBUSH AND SON.—Messrs. VINCE & VINE."

TO FLORISTS.—A young Lady seeks engagement as ASSISTANT in Shop or Nursery. Well up in Bouquets, Wreaths, Sprays, &c.—**A. B.**, 30, Lower Breck Road, Liverpool.

HOLLOWAY'S PILLS and OINTMENT.

—Influenza, Coughs and Colds.—In diseases of the throat and chest, so prevalent in our changeable climate, nothing so speedily relieves, or so certainly cures, as these inestimable remedies. These disorders are too often neglected at their commencement, or are injudiciously treated, resulting in either case in disastrous consequences. Whatever the condition of the patient, Holloway's remedies will restore, if recovery be possible; they will retard the alarming symptoms till the blood is purified and Nature consummates the cure, gradually restoring strength and vital nervous power. By persevering in the use of Holloway's preparations, tone is conferred on the stomach and frame generally. Thousands of persons have testified that by the use of these remedies alone they have been restored to health after every other means had failed.

MESSENGER & CO.'S New CATALOGUE of Greenhouses and Heating Apparatus,

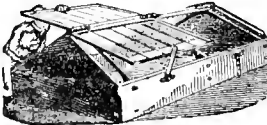

Just issued, will be found the most complete, practical, and reliable guide to all about to build, alter, or heat Greenhouses, illustrations of every description of Glasshouse, from the largest range of Winter Gardens to the simplest forms of Portable Greenhouses, Plant Protectors, and Garden Frames; also of all the best kind of Boilers, Hot-water Pipes, and all appliances for heating. This Catalogue, possessing hundreds of illustrations of all the latest improvements in greenhouse building and heating, is on a scale never before attempted. It should be in the hands of every one interested in gardening, as it contains many practical hints on the subjects of which it treats, the result of many years' experience. Price, 2s. post-free.

A large number of the illustrations are taken from greenhouses erected by us in various parts of the country; an inspection of this Catalogue shows, therefore, the efficiency of which has been well tested by actual use. The advantages possessed by us enable us to carry out work with the utmost promptness, and in the very best style, at prices which defy competition. Surveys made, and gentlemen waited on in any part of the country. Plans and Estimates free on application.

Sale—November 11.

BY ORDER OF F. SANDER & CO., ST. ALBANS.

NEW ORCHIDS

FROM THE NATUNAS ISLANDS.

NO OTHER COLLECTOR HAS EVER EXPLORED THIS GROUP.

SACCOLABIUM SANDERÆ (provisionally named).—A distinct and remarkable-looking species, with white and amethyst flowers, and strikingly handsome foliage.

COELOGYNE ERICSSONII (provisionally named)—This is without doubt the premier representative of the genus, provisionally named after our intrepid and indefatigable collector, Mr. C. Ericsson. A large white flowering variety, with long racemes.

A NEW DENDROBIUM, in the way of D. AMETHYSTOGLOSSUM.

Also a superb importation, in perfect condition, and containing many truly grand specimens of a CYPRIPEDIUM, reminding one of the Western Palmifolium.

BRASSIA LANCEANA, the long-tailed green and chocolate spotted OCTOPUS ORCHID; flowers often measuring 2 feet across.

SOBRALIA SPECIOSISSIMA. A new and remarkable SOBRALIA, with delicate lavender sepals and petals, and a terra-cotta red lip.

DENDROBIUM DICUPHUM, rare and beautiful. A PHAIUS with purple blossoms, from New Guinea. CYPRIPEDIUM ANNAMENSE (provisionally named).—A distinct and vigorously growing species, citron and white blooms, with purple blotches.

100 splendid Plants in Flower and Sheath of the true old autumn-flowering CATTLEYA LABIATA, &c., &c.

MESSRS. PROTHEROE AND MORRIS, will SELL the above by AUCTION, at their Central Sale Rooms, 67 and 68, Cheapside, London, E.C., on FRIDAY NEXT, November 11, at half-past 12 o'clock.

On view morning of Sale, and Catalogues had.

THE NURSERIES, BERKHAMSTEAD, HERTS.

VICTOR POTATOS (SHARPE'S).

This favourite first early Potato, suitable for any Garden, indispensable for Forcing and Early Borders, and likely to take the first rank amongst first early for market use. Quality and yield all that could be desired. One well-known market grower has this year had a yield of 15 tons per acre on a large acreage. London and Manchester salesmen speak highly of their quality, and report that Victors will keep their bloom and have a fresh appearance after being in the market some days, when other early Potatos have become discoloured and unsaleable.

The stock we offer is the true yellow-fleshed variety and not the white variety, which is often substituted.

Price per cwt. and ton. State requirements to

W. W. JOHNSON & SON, Seed Growers and Merchants, Boston, Lincolnshire.

In Chancery.

FRUIT TREES.—80,000 very choicest kinds. THE "EARLY RIVERS" NECTARINE.

A Seedling Nectarine raised by Mr. T. Francis Rivers, the earliest Nectarine existing, ripening twenty-one days before Lord Napier, measuring $9\frac{1}{4}$ inches in circumference, weight 8 ounces, freestone, brilliant in colour, flowers large.

This Nectarine is offered on the following terms, viz.: by Subscription, at £2 2s. each, provided that a sufficient number of Subscribers is received.

Strong young plants, in pots, will be delivered in March or April, 1893.

A First-class Certificate was awarded this Nectarine by the Fruit Committee of the Royal Horticultural Society, in July, 1892.

For Opinions of the Press, apply for Circular, post-free.

NEW SEEDLING PEAR, "CONFERENCE," RIVERS.

Certificated by the Royal Horticultural Society.

Fruit large, pyriform; skin dark green and russet; flesh salmon coloured, melting, juicy, and rich. Tree robust and hardy, making a strong healthy growth on the Pear and Quince stocks. Very prolific, a good garden and orchard fruit, and a valuable market sort. It ripens from the first to the third week in November.
 Strong trees, 3s. 6d. each.

THE

Gardeners' Chronicle.

SATURDAY, NOVEMBER 5, 1892.

OXFORD, AND ITS GARDENS.

I WENT to Oxford lately, not to look at its architecture, which I do not pretend to understand, but to look at its gardens, which I do. I was asked by a friend what I found in Oxford—were there any gardens there? And on my saying she possessed one of the oldest botanical gardens, he replied that he knew the kind of garden; such gardens made him sad. Certainly, some botanical gardens are not particularly exhilarating to horticulturists. Why? Is there any reason why a professedly botanical collection of plants should look worse than other collections?

The botanical gardens of Oxford belong to the University [in part, partly to Magdalen College, we believe], which ought certainly to take a pride in the possession of a garden founded over 260 years ago, and should spare no reasonable pains to make it as interesting and instructive as possible. To all appearance, they do nothing of the kind. If I point out defects, I will also offer some advice to that august body the university authorities—for they need both.

The gardens look their age. Five acres of ground, surrounded by a thick high wall, with a few little houses, a library, and a barbarium. They have grown very little since Bobart, their first Curator, presided over them. Most of the houses are venerable structures, with, no doubt, an interest for the antiquarian, but absolutely hopeless for the healthy cultivation even of a Pelargonium or a Coleus. The two or three small modern houses are better, but they are crowded with all kinds of plants, which might be able to look themselves if they had elbow-room.

Does the university require for teaching purposes a museum of living plants, representing the most interesting forms of vegetation? Surely, the answer must be—yes. If such a collection of plants has any value anywhere, it must be at a place where thousands of the country's most favoured sons are educated. It is not necessary in this place to urge upon all who have to do with education that a knowledge of the vegetable world is of primary importance, or that a botanical collection of living plants should form an important item in the equipment of a university.

A garden which served its purpose 200 years ago, when the science of botany was in its infancy, is scarcely likely to serve the present time. Instead, however, of containing a good well-managed representative collection of plants, it is crowded with all sorts of oddments, such as I suppose the Curator can beg or borrow; it is as badly equipped as it well can be, starved for funds, badly manned, and cramped inside those grim old walls.

Some one told me that there was a growing feeling among the "Dons" that the gardens are not worth maintaining. As they are now, possibly not, for

they are no credit to the scientific side of the university. They should be enlarged, enriched, and brought up to the times. Now, the sister university, Cambridge, which by the way I am told, is much poorer than Oxford, maintains a garden four times as large as that at Cambridge, and at least ten times better equipped in regard to houses, labour, &c. Cambridge has kept abreast of the times, and her botanical collection is not surpassed by that of any similar institution known to me. Oxford, meanwhile, has been asleep. There is plenty of space for the expansion of the garden, both beyond the river and into the Christchurch meadows. A new range of glass-houses should be erected, a rock garden made for the cultivation of choice herbaceous and alpine plants, and a proper arboretum started. The vegetation of the temperate regions is very poorly represented there now, and there is no room in the present houses for a respectable collection of tropical and subtropical plants. I daresay the present director or curator, or whatever he is, does the best he can under the circumstances. But the collections appear to be totally unworthy of Oxford University.

THE PARKS:—The park at Oxford, which was laid out and planted by the late curator of the botanical gardens, Mr. Baxter, and laid out well, is, or was, full of interesting trees and shrubs, many of which are now perishing for want of attention. The best constructed garden in the world will, in time, become a laughing stock if it be not carefully tended and kept in order by some one who understands it. The services of a good landscape gardener are now much needed in the Oxford Parks. Beautiful views and compositions are being shut out or spoiled by unchecked growth or misplaced trees; or worse still, by newly-planted ones. Some poor little Deodars, which have been planted in a bleak exposed field, tell a plain tale. God tempers the wind to the shorn lamb, but who will temper it to those poor Deodars? Why not plant Cotons there? Still, the park is a pleasant place, with its wide stretches of turf for cricket and football. It only requires a capable keeper.

COLLEGE GARDENS:—The college gardens have a beauty of their own—a beauty which owes much to architecture. St. John's Gardens were the most beautiful I saw. They are five acres in extent, and are said to "exhibit the results of centuries of careful cultivation." There are some good trees and shrubs, and some very poor ones—picturesque compositions, too; but there is need here, also, of the hand and eye of the garden-artist; here a tree requires lopping, there a group wants strengthening, and one or two recent additions want removing. That little caricature of a rockery, also, is out of place.

It is the same all over. The grand avenue of Elms in the Christchurch meadows wants the care of the tree doctor to save them from deadly fungi and overcrowding. The delightful walk along the Cherwell might be made still more delightful, if a few openings were made in the tree-belt here and there, to let in the pictures of spire and tower and tree. Everywhere there are beauties, architectural and sylvan, but that art which doth mend is needed to show them to advantage.

Such a town as Oxford requires the assistance of a thoroughly qualified landscape gardener, amateur or professional, who would watch over and make the most of the town, its buildings, and its gardens. Such a man would be able to make the town still more attractive even than it is now. It is unfortunate that so many people have the same view with regard to garden-making as to farming, namely, that every man can do it, if he likes. There are plenty of born farmers, perhaps, but there are not many who know instinctively how to make beautiful pictures out of trees, buildings, water, and grass. Oxford cannot learn this truth too soon. *Tradescantia*.

NEW OR NOTEWORTHY PLANTS.

MILTONIA CLOWESII GIGANTEA.

This is a very handsome and distinct form, which is now flowering in the collection of Major Mason, The Firs, Warwick. It differs so much from the

type as at first sight to suggest its being the result of a cross with some other species, but comparison shows that the essential characters are the same in both. The chief differences in the variety gigantea are that the spikes are shorter, the flowers larger, all the segments broader, and the sepals and petals obtuse, and not acuminate; in fact, more nearly resembling in form those of *M. candida*. The sepals and petals are of an Indian yellow tint, spotted with chestnut-brown, and they are purple coloured at the base. The labellum is very broad, purple coloured at the base, and of white, which with age changes to a sulphur-yellow, hue at the tip. *J. O'B.*

ORCHID NOTES AND GLEANINGS.

ORCHIDS AT PARKFIELD, HALLOW.

ON making a recent visit to the above charming place near Worcester, I was not only struck with the beauty and general high keeping of the gardens, but with the very fine collection of Orchids, most of them large specimens of their kind. Amongst those in flower at that time were the lovely orange and crimson-lipped *Cattleya aurea*, the pearly-white petalled and ochry-yellow throated *C. Gaskelliana albens-odorata*; *Laelia elegans Turnerii*, with its lovely deep mauve petals, and violet-crimson lip. Splendid plants of *Vanda teres*, *V. Hookeriana*, and *V. corulea* were in flower, and the glorious *Dendrobium Phalenopsis Sanderianum* was present in bloom in quantity. Others in bloom consisted of *Sobralia xantholeuca*, *Cycnoches chlorochilon*, *Odontoglossum grande*, *Vanda Kimballiana*, *Dendrobium formosum* and *D. Statterianum*, *Vanda Sanderiana*, *Laelia elegans Schilleriana*, *Epidendrum prismaticum*, *Masdevallia Harryana*, *M. Daviesii*, *M. Chimera*, *M. caudata*, *M. Schlimii*, *Laelia pumila*, &c. Mr. Catt also grows magnificent Pineapples and other subjects. *J. Udale*.

VANDA CERULEA.

A photograph which has been sent us, as well as a fine spike of this handsome Orchid, show how successfully it must have been grown in T. W. Thornton, Esq.'s, garden, Brockhall, Weedon. The plant had several spikes, the largest of which had fourteen flowers, each $4\frac{1}{2}$ inches across. The intensely blue venation, the tinge on the segments of the flowers, and the bright violet colour of the lip, make it one of the most beautiful of Orchids; but while some persons grow it well and easily, like Mr. Thornton, others have but poor success with it.

SCHOMBURGKIA LYONSII.

This rare and handsome species is now in flower with Joseph Broome, Esq., High Sheriff of Carnarvonshire, at Sunny Hill, Llandudno. It has a large and elegantly-arranged head of flowers on a stout spike 3 feet in height. Each flower is borne on a foot-stalk about 4 inches in length, the broad-petalled flowers themselves being rather under 3 inches across. They are pure white, charmingly spotted, and marked with violet-tinted crimson. It is a grand Orchid, but seldom found true to name, the common *S. crispa* and other species being generally sold for it. An almost perfectly circular-flowered form of *Vanda Sanderiana* is in flower in the same gentleman's collection. *J. O'B.*

KEW NOTES.

GLADIOLUS OPPOSITIFLORUS.—This very interesting plant has lately been introduced to Kew, where it is now in flower in the Cape-house. It is the tallest species in the genus, the Kew specimens being 6 feet in height, very sturdy, the base as thick as a man's little finger, the lower $\frac{1}{4}$ feet clothed with thick, rigid, ensiform leaves, 2 feet long and $1\frac{1}{2}$ inch wide, prominently nerved, narrowed to a tapering point. The spike of flowers is 2 feet long, and there are ten flowers fully open on one spike, with sixteen more in bud. Each flower is $2\frac{1}{2}$ inches across, the segments 2 inches long, the three upper ones each $\frac{3}{4}$ inch wide,

the three lower $\frac{1}{2}$ inch wide, wavy, recurved, pure white with lines of deep amethyst on the three lower segments, and a tinge of the same colour at the base of all the segments. Another plant has a shorter spike, and flowers lined and shaded with rose; and a third shows a difference in the size and marking of the flowers. For the reintroduction of this plant, we are indebted to Professor MacOwan, who sent six corms of it to Kew last July. It was found growing in the Transkei, and is said not to be uncommon about the Kei River.

Herbert first described this species in Lindley's *Botanical Register*, 1842, where he says it was erroneously known in gardens as *G. floribundus*. He also says it was found in Madagascar by Forbes, who collected for the Horticultural Society, and that "it is also, perhaps, a native of Port Natal." But the chief interest in this plant lies in the fact that Herbert believed it to be one of the parents of *G. gandavensis*. He says:—"The *G. gandavensis* of gardens is a cross between *G. oppositiflorus* and *G. natalensis*; so also is *G. ramosus*, of gardens, between *G. oppositiflorus* and *G. cardinalis* or *cardinalis-blandus*." In his paper on "Hybridisation amongst Vegetables," *Journ. Hort. Soc.*, ii., p. 89, he says:—

"The showy *G. natalensis*, which endures more frost than any of the southern Gladioli, though it suffers much from July rains in many positions, has been freely crossed by myself, by Mr. Belfield, by Mr. Bidwill, and by cultivators on the Continent, with *G. oppositiflorus*, a Madagascar plant, found, perhaps, also in Caffraria, and often called improperly in the shops *floribundus*, an old name for a very different plant. The cross named *gandavensis* has been figured in the beautiful periodical work of M. Van Houtte, of Ghent. It is there stated erroneously to have been raised between *G. natalensis* and *G. cardinalis*. It flowered at Ghent for the first time in Europe. . . . The cross erroneously stated to have been made between *G. natalensis* and *G. cardinalis* if not absolutely impossible, is so difficult, that repeated attempts made during successive years by myself and others have in all cases proved abortive."

On the other hand the raiser of *G. gandavensis*, Bedinghaus, says he obtained it by crossing *G. psittacensis* and *G. cardinalis*. This he did in 1837. Mr. Baker, of Kew, is also disposed to believe that Herbert was wrong.

It would be interesting if the cross which Herbert declares produced *G. gandavensis* could now again be made. If anyone has *G. natalensis* in flower, or likely to flower, he might send a plant or flowers of it to Kew. The exceptional height and vigour of *G. oppositiflorus* ought to commend it to the special notice of breeders of Gladioli. At the same time, it is a first-rate garden plant in itself. Herbert called it *oppositiflorus* from the flowers being arranged exactly in two rows, one on each side of the spike. Of course the flowers are alternate. A figure of the Kew plant has been prepared for the *Botanical Magazine*. *W. W.*

A TRAVELLER'S NOTES.

(Continued from p. 470.)

[On leaving Calcutta, Mr. Veitch proceeded to Rangoon, which presented little of horticultural interest. Mr. Veitch then went on to Penang, where he arrived on January 21, 1892.]

PENANG, JANUARY 21.—Early on the second day of my stay, we started to go up Government Hill on ponies. The base of the hill is close to the gate of the public gardens, and but a few hundred yards from Mr. Curtis' house. The ascent is very steep, and the height of the hill 2500 feet. On the summit is one of the Governor's houses, and a signal station for incoming and outgoing vessels. Near here Mr. Curtis has a vegetable garden, where he is tolerably successful with most things. Peas and dwarf Beans are fairly good, and Parsnips, Lettuce, and Onions are found to be best from acclimatised seed. Chinese Radish is grown, as is a Chinese Cabbage, from cuttings; it has no heart, and though not of first-rate quality, is yet valuable where so few vegetables are found.

A very handsome Conifer growing on the summit of this hill is *Dacrydium elatum*; it is of regular pyramidal form, and will grow from 20 to 30 feet.

Its foliage is thick, and of two forms, like a Juniper. *Podocarpus chinensis* also does well, as does *Grevillea robusta*, of which I saw some fine tall specimens planted but 2½ years ago. *Spathodea campanulata*, with large orange and scarlet cup-shaped flowers, was in bloom, and I had the satisfaction of seeing on the trunk of a tree a fertile frond of the true *Platycerium bifforme*—a curious kidney-shaped structure, several inches in diameter. Mr. Curtia told me it was only a small example; when seen, which is not often, they are usually much bigger.

Perak. Near the house is a nice row of *Juniperus virginiana*, growing freely.

The highest point in the island is only two miles from Government Hill—it is 2750 feet high.

Descending the hill on foot, for it is too steep to ride, one passes the new Sanitarium, a strong, granite-built house, for the use of Government officers. Many other bungalows are also dotted about the hill. A curious Myrtaceous plant, much resembling a *Cauarina*, *Baekia frutescens*, grows near the top of the hill; it is as unlike a Myrtacea as anything well

is also used for this purpose. *Mimosa pudica* is here, as in Ceylon, a most tiresome weed, almost impossible to eradicate; it is pretty abundant on Government Hill. The most interesting of all to me was the thick undergrowth of *Gleichenia—flagellaris*, *dichotoma*, and *longissima*—the latter not so common as the two former. They all grow with great luxuriance, and form magnificent leaves, those of *longissima* being many feet long. In every direction up the sides of the hills there is a thick carpet of these handsome plants.

I also saw many specimens of *Dipteria (Polypodium) Horsfieldii*. It produces its large round leaves in shade high up in the hills—it is a most striking picture.

At an elevation of 2000 feet, Mr. Curtia has constructed on the side of a hill an experimental garden for native and introduced fruits. It was commenced in 1885, but Mr. Curtia does not consider it has yet had a sufficient trial to speak about results. He finds, however, English fruits will be of no value—a result that one can scarcely be surprised at.

Round this garden and alongside the road is a hedge of *Bambusa nana*—forming a very thick and useful boundary mark. This and *Pithecolobium dulce* are the two finest hedge plants in the island.

Areca palms—*Areca Catechu*—with their tall thin stems and small tufts of leaves, are most common; from time to time we met a Chinaman cutting down the bunches of large red seeds for chewing purposes. A hooked blade at the end of a long Bamboo is the means employed. *Duriana*, *Mangosteens*, *Cloves*, *Nutmegs*, and *Cocoa-nuts*, also are very numerous.

Of the two latter, we saw large plantations. The Nutmeg is really most ornamental, with its large thick, rich green foliage; the head is regular and pyramidal. A few Mangoes are to be seen, but not the quantity one sees in certain parts of India; and Bread-fruit—but not always the best variety—the well-known seedless variety of the Malaccas. Pine-apples, escaped from cultivation, are common, often hanging over the path from some rock above.

In descending we made our way through the Azer-etam Valley to the village of the same name, from whence we took a "gharry" back to the gardens. Looking at this valley, enclosed on all sides by the hills, was a pretty picture; all one saw were acres of the wavy heads of *Cocoa-nuts*, cultivated for commercial purposes by Chinese, whilst on one side up the hill to the forest boundary were plantations of Spices, broken here and there by masses of the Betel-nut (*Areca Catechu*) and other trees.

This forest boundary, under Mr. Curtia's charge requires a little explanation. It is a large portion of the island on the summit of the hills, which the Government has taken, and in which they refuse to allow anything to be cut. Before this was done, enterprising planters, chiefly Chinamen, kept on cutting down jungle, always pushing still higher and higher up the hills, for their Spice groves, until there was danger of the rainfall of the island being affected. Within what is known as the forest boundary, no one may now cut down a tree, and enforcing this rule gives Mr. Curtia on the average one prosecution a week.

He has occasionally to make tours through these woods, and has at certain points watchmen to inform him of any too-enterprising planter. Driving home from the foot of the hill, we passed through groves of *Cocoa-nuts* as rich and as numerous as in Ceylon. The heat is very great—it is now the hottest season, but the coolest at night—rain is much wanted for the vegetation; but there is no danger of water failing for the inhabitants, as the island possesses a magnificent unfailing water supply, doubtless owing to its hilly character. *J. H. Veitch.*

(To be continued.)

CHRYSANTHEMUM JOTTINGS.

(Continued from p. 536.)

CHRYSANTHEMUMS AT LEWISHAM.—Many persons might wander over this south-eastern suburb of London, and have a difficulty in finding Mr. H. J. Jones' wonderfully fine show of *Chrysanthemums*; or, if fortunate enough to find it, would regard it as inconceivable that so brilliant a show of flowers could be found within the purlieus of smoky London. How much do town dwellers owe to the *Chrysanthemum* for its remarkable capacity to produce beautiful flower shows, such as is this one at Lewisham at so gloomy a time of the year as is November! The

W.C.S. 52

FIG. 84.—A PLANT OF NEPENTHES RAFFLESIANA. (SEE P. 561.)

From the summit of the hill one can see across to Province Wellesley on the mainland, with Kedah and Perak in the distance. The former, an English possession, is a fertile stretch of land, chiefly under Tapioca, Sugar-Cane, and *Cocoa-nut* cultivation. Some of the estates are very large, employing 2000 coolies. In Perak much Coffee is successfully grown, but the climate is bad. I met one man who recently lost 100 coolies out of 500. He himself is ill, and has just been ordered home.

Turning from the top of the hill to descend, we passed a little thatched house where Mr. Curtia keeps a few plants for the Governor's use. He has there some fine *Phaius grandifolia*, collected in

can be. Tea Roses grow well, but hybrid perennials are rather failures. The vegetation on the hill is very rich; great trees with tall, straight stems are common. The most important order, both for commercial value and on account of numbers, is the *Dipterocarpeae*. Some of the trees belonging to this order are magnificent. Many *Eugenias* are also to be seen.

A common Palm on the hill, as well as in the tidal swamps along the coast, is *Eugeissonia tristia*. It is stemless, all its straight *Kentia*-like leaves springing from the base. It is of great economic value in the island, its split leaf-stalks as well as its dried leaflets being extensively used for thatching. *Nipafriticans*

day of my visit was a wretchedly wet one, and whilst without all was misery and dirt, it was indeed a change like to a scene in a fairy play to suddenly turn from the external damp and smoke into the pure bright atmosphere of Mr. Jones' fine show-house, and there see what is, I really think, without exception, one of the finest *Chrysanthemum* shows to be found anywhere in the kingdom.

The chief show-house is 103 feet by 25 feet, a light and fairly high span; an alley runs through the centre, and on either side are ranged, eleven rows deep, some 1250 plants, none very tall, but all in good-sized pots, in robust health, and blooming, or about to bloom, superbly. Overhead there is strained a sheet of tiffany, which, whilst catching and retaining until dried, the moisture which usually settles so freely on the glass roof, and then drips on to the flowers—this prevents incalculable harm being done by drip. It also checks the cold force of the down draught from the top ventilators, which are freely open, and whilst softening the air, also distributes it equally all over the house. Still farther, this tiffany-screen very materially interposes for the collection of blacks—the terror of *Chrysanthemum* growers in towns; so that serving such diverse useful purposes, its value can hardly be too widely known. As an ordinary trade grower, Mr. Jones, of course, has stock of all possible varieties, but equally, as an enterprising one, he has to keep pace with the exacting requirements of the times for novelties, hence his collection is very rich in these, and about the middle of November—for here as elsewhere, all *Chrysanthemums* are rather late—growers will have as good an opportunity as perhaps can be found anywhere to become familiar with the best of the new ones. Of varieties that made great reputation last year, Vivian d'Morel, Wm. Tricker, W. H. Lincoln, M. R. Bahuant, Louis Boehmer, and many others that are legion. Of new ones there is legion also. Very noticeable, for instance, is a white form of Louis Boehmer, that will supersede Mrs. Alpheus Hardy, because it has all the robust character of its originator. Then a grand flower, and not unlikely to be the premier flower of the season, is Colonel W. Smith, colour, chestnut shaded red; petals somewhat incurved; a very large and massive flower. Mrs. Harman Payne is another very fine French variety; colour, deep rose; petals incurved. T. H. Dennis is a grand loose flower, style of E. Molyneux, and somewhat in colour, but promises to be a broader flower. President Carnot is like M. R. Bahuant, but has more gold on the reverse of the petals. Unfortunately most of my notes on novelties have unaccountably disappeared, and in consequence my advice to all who want to see a first-class display of new sorts is to go to Lewisham, for Hither Green is not more than a mile from the Junction station. In a second large span house there is a huge batch of later bloomers, also a grand lot of show *Pelargonium* specimens, Chinese Primroses, and various other things, and in another house a brilliant display of zonal *Pelargoniums* in full bloom. *A. D.*

VICTORIA PARK.

It is now twenty-eight years since the first exhibition of *Chrysanthemums* was held here, and one is always sure of seeing a display worthy of so long a history. This year the plants are wonderfully fresh and healthy, the flowers large and charming, whilst the foliage is green and robust. In the span-roofed house, that has been used for this kind of display for some years past, Mr. Gibson has, under the charge of Mr. Large, about 3000 plants, and these are arranged in sloping groups on either side, with a wide path running down the centre. The show was opened on the 22nd ult., and is not yet at its best, perhaps because the atmosphere is more moist in this vicinity than in other parts, which will result in the wood taking more time to ripen. A few new varieties have been added to the collection, but, on the whole, the old tried varieties have been relied upon to a large extent. The new incurved M. R. Bahuant was remarkably fine, and the peculiar

green-coloured Florence Davis is looking as well as we have seen it. W. Tricker is a new rose-coloured Japanese, slightly incurved, and, judging it from the specimens observed here, it is of good promise. By far the largest bloom of Mrs. A. Hardy that we have noticed was just passing its best, which was to be regretted, for had it been in good condition about ten days later, many hundreds of people would have had an opportunity of seeing it. The other flowers of the same kind are good, but not of special interest. Louis Boehmer is much more easily managed than its white relative. A plant of Edouard Audiguier, that had been cut back in May, had three very fine blooms upon it, and being dwarf, it would be most useful.

Some plants of Stanstead Surprise once more exhibit the wonderful different blooms that are obtained from crown buds, and from terminal ones. A plant, where the crown buds had been "taken," had produced good-sized blooms, which were nearly white, only a slight marking of rose or pink being present, whilst the other carried flowers, from terminal buds, of a rich crimson. Mr. W. K. Woodcock appears to be a useful and pretty Japanese variety; it is new. Mr. J. Laing was doing well, and its crimson blooms looked exceedingly handsome. An old acquaintance was there in Old Chang, and quite justified its position. Mrs. F. Jameson was remarkably good, and in passing we may observe that it should be found in every collection. Others are in excellent form, but readers will do wisely if they go and see for themselves, remembering also that it is some distance from the station called Victoria Park—Cambridge Heath Station, on the Great Eastern Railway, is much nearer.

MR. W. WELLS'S NURSERY AT EARLSWOOD.

About a mile and a half from Redhill Station, and adjoining that of Earlswood, on the London and Brighton Railway, is the *Chrysanthemum* nursery belonging to Mr. W. Wells. Some 400 or 500 varieties are to be seen here, but many of these were not in flower at the time of our visit. The plants all look healthy and vigorous, and the wood appears fairly well ripe, notwithstanding that—as is common in most places—such a number have been grown that it has been impossible to give each that amount of space during the later summer months that they ought to have. In the range for large blooms, resulting in the tall—and not too presentable—plants that are everywhere met with, it is a relief to meet a grower like Mr. Wells, who maintains a decided love for the Pompons, and especially for the single varieties. A fair collection in each of these groups are here to be seen, and some of them having been grown without any disbudding are beautiful and exceedingly decorative objects. Miss Mary Anderson is known to most persons having any pretence to *Chrysanthemum* knowledge as being a beautiful white single, wonderfully adaptable for most kinds of decorative purposes. Scarlet Gem is also a very pretty bright variety of good habit, and very free flowering. May Wells, a seedling raised here from Miss Mary Anderson and Scarlet Gem, is a deep crimson scarlet, that cannot fail to please anyone interested in this section. All the single varieties are best on the late buds, and when they have not been disbudded. A large number of seedlings in this section and in that of the Pompon will be named and sent out next spring. Of the usual large-flowering varieties, there is also an extensive and choice assortment, including a rich group of the newest varieties. Mr. Jno. Lambert was in good form, and Stanstead White looked charming, but the large and lovely rose-coloured Wm. Tricker will soon be a most popular favourite. Its colour is so pleasing, and its form is good. Coronet, an improvement on Thunberg, is a new Japanese of richest golden-orange. The appearance of the flowers is a little careless, the centre petals are slightly incurved, and the outer ones reflexed. It is large and handsome. G. C. Schwabe, a seedling from E. Molyneux, is a Japanese of large size, described as of good colour—carmine-rose, with gold centre—but not perfectly out at

present; it may be valuable. La Chirre is a very fine golden-yellow Japanese, of canary-yellow, and is said to do very well, if treated on the pinching method. A seedling incurved, somewhat like Jeanne d'Arc, but of purest white, may prove to be of first-rate importance under good culture the second year. Mrs. Nisbet is a very pretty Japanese, reflexed variety, of purple-amaranth, with silver reverse, but it requires to have the wood thoroughly-ripened. A variety of the Mrs. Alpheus Hardy type deserves notice, if only on account of the cumbrous name to which it has been attached. Marchese Bardo Corsi Salviati, should be sufficient introduction for anybody; it has long broad petals, white, with cream centre, reverse of petals light rose. The plant is of strong habit, and—one need hardly remark—of Italian origin.

Mr. W. Wells believes that he has fixed a white sport of Vivian d'Morel, and has already presented it before the committee of the National Society, but at present no award has been secured. The plants are growing side by side with the others, and have been propagated from the white sport of last year. To an ordinary visitor the sport appears to be quite fixed, and if such should prove to be the case, the acquisition will be a very rich one indeed.

MR. GEO. STEVEN'S NURSERY AT PUTNEY.

Mr. Steven's plants look well at St. John's Nursery, and he thinks he never had a finer lot; but, situated so close to the river as he is, one cannot say how he will fare when he has to take his plants to the Aquarium to take his place among the competitors for the group. Anyhow, we were given to understand that, if the fogs are not too unmerciful, that he would be there. There are not many new varieties here, and Pompons and single forms are almost excluded. A very great number of Japanese are grown for furnishing blooms for market, and for this purpose one could notice as many as three hundred plants of Ed. Molyneux, a like number of W. H. Lincoln, and large batches of later stuff, including a good lot of Ethel. A good October-flowering Japanese was there in Gorgeous, a decided improvement on Peter the Great. Sunflower, a new loose-looking Japanese that one can hardly praise too highly, was carrying good blooms, as was also the velvety crimson Jeanne Delaux. The incurved varieties had hardly begun to open when these notes were taken, but some thoroughly plump buds of good size promised much. These were Lord Alcester, Golden Empress of India, Empress of India, and Mr. John Lambert. Altogether, there were about three thousand plants in this well-known "mum" establishment, and their care is evidently the subject of Mr. Steven's closest attention.

MESSRS. PITCHER & MANDA'S NURSERY.

At the United States Nursery, situate at Hextable, near Swanley, Kent, we found a good display of many of the new varieties. The space at command here precludes the possibility of growing a very large number of plants, hence a few only of a variety are allowed. Consequent upon good culture, the plants present a healthy appearance, and many of the blooms are larger than have been noticed of the same varieties in many places. The grower here has subjected untried varieties to treatment in exceedingly small pots; many of the newer and less known of them we found in 6 inch and 7-inch pots, bearing one bloom in most cases, and with foliage clothed to the bottom. It was surprising what good flowers were so produced; but it is also argued, that if a variety will succeed with such treatment, and produce good bloom, no fear may be entertained when, another season, it is allowed a more liberal treatment. Of course, at this establishment the effort has always been to secure "hairy" ones, after the manner of Mrs. Alpheus Hardy, and a great number of such are now to be seen here. W. A. Manda, which secured a First-class Certificate at the National *Chrysanthemum* Society last week, is a rare acquisition. In colour, a fine yellow, and its petals quite hairy; it will be very popular among the hairy Japanese. Miss Anne Manda is recom-

mended as an improvement upon Mrs. Alpheus Hardy; in colour and character it much resembles that variety, but is said to be a better-built flower, and of stronger constitution. George Savage is an incurved white, and a seedling from Mrs. Alpheus Hardy; with a greenish centre, and a few hairs at tip of petals, it may become a good thing. Several seedlings, at present unnamed, also promise much, especially two that we noticed, being good in colour, and quite characteristic of the group. A bronze hairy one is supplied in H. Ballantine, a Japanese, which will be popular with some people.

Of the smooth kinds, particularly noticeable were Robert Flowerday, a good and distinct Japanese, with broad petals; the colour is crimson-purple, with silver reversed margins, and the tip of petals are green. The Tribune, which will be sent out next spring, and is a large primrose-coloured Japanese, very full, and broad-petalled; Primrose League, a little like Florence Davis, but the green colour in which it opens turns to primrose rather than white; it is also larger, and more easily done. Florence Davis was here in good form, and W. H. Lincoln had especially large flowers, but those of Col. W. B. Smith were the finest we had seen. Mrs. E. D. Adams is a large Japanese with very long petals, and good white. The variety that we mention last is Geo. W. Childs, which obtained the Gold Medal last year for the best seedling, offered by J. R. Pitcher, Esq., in America. It is a large, massive flower, reflexed, and of broad petals; colour, a rich velvety-crimson, with no other shade observable. It is certainly a handsome variety, and of the most popular of colours.

MESSRS. CANNELL & SONS, SWANLEY.

Here are Chrysanthemums in endless variety, and most of them new. In one large span-roofed house there are about 3000 in 500 varieties, and this number represents the amount of new ones possessed by the firm. Altogether, new and old, there are something like 1200 varieties, and yet these are so far distinct, as to be recognised by one who is constantly among them. The plants are so far like other collections, in that they are a little later than usual, and that they already feel the injurious effect of the damp weather that has lately obtained. Bright, however, is the display, and a brighter one is promised by the immense plump buds that may be seen on most of the plants, which are well-furnished with bold strong foliage. The first noticed was Golden Ball, a new Japanese yellow, with full centre, not large, but very fine. This received an Award of Merit at the meeting of the Royal Horticultural Society on Tuesday last. Ethel Paul, a white Japanese from America last year, in its first appearance is like Avalanche, but finishes up a complete snowball. A first-rate variety is Mrs. H. W. Goulden, a new incurved. Its colour is exceeding pale lilac, very delicate; the petals are large and broad. Delaware is in fine form, and this new Anemone-flowered is a valuable variety. Ida Longhi is a new Japanese, large-flowered and curious; has the appearance of being striped, white and rose. Some immense blooms of the large white Japanese of last year, Mdle. Marie Recoura were noticed. It has very long petals, and a somewhat loose appearance. Messrs. Cannell have a very large stock of that excellent Japanese, Colonel W. B. Smith, bearing some good flowers of great substance. A very pretty and delicate variety is Harry Balsley; it has long and broad petals, and the colour is very pale flesh, and promises to become a handsome thing. A new Japanese, of continental origin, is Erneat Verdert, and promises to be extremely useful for growing in small pots and for decoration. In colour it is a good crimson, very like Jeanne Delaux. Julius Roehrs looks as if it may become as large as a Cabbage; at present it is not fairly out. Here were some good blooms of Geo. Wm. Childs, the lovely gorgeous Japanese; Vice-President Calvat is another new one of merit, a Japanese, it has broad petals of crimson-red, with gold reverse. Mr. Cannell hopes great things from

a very fine Japanese called Beauté Toulousienne. It is velvety-crimson, with gold reverse, something like Wm. Holmes; it is a great improvement on that variety, being much better in colour, and the gold reverse very much more distinct. We have not space to refer to other novelties at this establishment, but may say that already Mr. Cannell has got some thousands of cuttings in small pots, and propagation is going on as rapidly as possible in a well-appointed nursery.

FORESTRY.

PLANTING, AND CHOICE OF PLANTS.

PRACTICAL experience and observation tell us that there is a close connection between trees and the class of soil in which they delight to grow, and as plantations of any great extent generally contain a variety of soils, the planter should exercise his judgment in the selection of his trees by planting each kind on the class of soil, and situation, most conducive to their requirements. Good loamy soil of a loose open texture will grow hardwood and coniferous trees, either mixed or in masses. Thin, warm soil of a calcareous nature is best adapted for Beech, Birch, and others, as well as for hardy evergreen coniferous trees; loose open ground, with a small mixture of clay and organic matter, is suitable for the Larch and others; stiff clay soil is best adapted for the Oak, and although this is not a Larch soil, yet it will grow that tree to a useful and profitable size, so that it may be planted among the Oaks as a nurse, and to be cut out in the course of thinning, to give space for the Oak as the principal crop. The Oak dips its roots deeply into the subsoil in search of food, while the Larch spreads its roots principally along the surface, so that both trees can be grown during the early stages of their existence in the same plantation with advantage. On bare exposed situations it is a good plan where the ground is suitable for the Oak to plant Scotch Fir and other hardy Pines a few years in advance of the Oaks, for although the Oak is a hardy native tree, yet it is vastly improved in early life by shelter. When this plan is adopted, the pits for the Oaks may be dug at the time of planting the Firs, leaving the stuff excavated in a rough lumpy state on the edge of the hole, so that it may become pulverised by the weather, and the fertility increased by exposure. *J. B. Webster.*

ROUND BIRMINGHAM.

(Continued from p. 525.)

THE UPLANDS, SELLY HILL, is the residence of Charles Winn, Esq., an enthusiastic amateur, especially fond of Orchids, and is pleasantly situated. A pretty, although not extensive, garden surrounds the house. Conducted to the Orchid-houses by the amiable owner, we found that the species and hybrids of *Cypripedium* formed a leading feature of the collection, upon which much care in cultivation is bestowed, and in making new crosses, several of which have proved to be valuable additions to the genus, notably the handsome *Cypripedium Winnianum* × (*villosum* × *Druryi*); the pretty *C. Edith Winn* × (*Stoneli* × *purpuratum*); and the dark and richly-coloured *C. Cleopatra* × (*œnanthum* × *Hookeri*). Other promising crosses of *Cypripediums* made at the Uplands are approaching the size and age at which they will flower; and in other genera intelligent cross-fertilisation and careful culture of the plants after raising are about to have their reward.

Among those that may soon be seen in bloom are two very remarkable crosses, viz., *Cymbidium Mastersii* × *C. giganteum*, and *C. eburneum* × *C. giganteum*, both of which should certainly be handsome novelties. (See Report of the Orchid Committee, p. 566.) Other crosses of *Cymbidium* are coming on well, and the plants of the pretty *Dendrobium Nestor* × and *D. Aspasia* × have flowered, the former displaying a very curious variability in the growth of the several plants, some being pendent from the first, while others go up erect until the weight of the pseudobulbs bends them over.

Cypripedium Harrisianum × *C. Sanderianum* is

another hybrid of which much is expected, and the plants of the so-called *Thunia Benaoniae*, Winn's variety, exhibit still more beautiful flowers than those on the plant shown at the Royal Horticultural Society when it first opened. In growth it is stouter, and in stature taller than *T. Bensoniae*, although the cross has apparently only affected the flowers in relation to that species, in size and richness of colour, Mr. Winn's hybrid being far the better.

Of other hybrids, chiefly *Dendrobiums*, Mr. F. Oliver, the gardener, took down from the rafters of the house where they were suspended, many other remarkable crosses; but as they will doubtless be recorded as soon as they flower, it is not necessary to enumerate them here. In the *Cypripedium*-house we found a fine collection in robust health and large, some of the handsomest, such as *C. Morganiae*, plants of great size. A number of varieties of *C. Harrisianum* were in flower, of which *C. H. splendens*, *C. H. giganteum*, and *C. H. nigrum* were the largest and most distinct. The forms of *C. Ashburtoniae* also displayed a good deal of variety; and of *C. callosum* and *C. Curtisii*, which are noble species when grown as at The Uplands, many were in bloom. Others noteworthy, either by their fine growth or the beauty of their flowers, were *C. grande atratum* ×, *C. Spicerianum*, of which there were many plants; the quaint and pretty *C. Chamberlainianum*, *C. Ainsworthii* ×, *C. Crossianum superbum* ×, *C. leucorrhodum* ×, *C. Doris* ×, *C. Lawrenceanum*, *C. cardinale* ×, the varieties of *C. insigne* and of that favourite, *C. œnanthum*, which has few equals in its section. Here, too, we observed that charming variety, *C. Aylingi* × (the original plant), *C. vexillarium* ×, *C. Niobe* ×, and others of the *Fairrieanum* crosses, among which an indifferent one is not likely to appear.

The long *Masdevallia*-house was next in importance, and here are found most of the handsome forms in the best of health, a few being in flower, and the *Harryana* section promising a great show in due season. Overhead were suspended those plants which belong to the *Chimæra* division, among them several forms of *M. Chimæra*; and of *M. bella* and *M. Roehlii* in bloom. Here, too, was observed a plant of the true *M. Winniana*, which originated at the Uplands; and it needs but a glance to estimate its superiority to the rest of its class. Its massive flowers are almost wholly of a peculiar shade of crimson; and the tails of the segments are 6 inches long—truly a remarkable flower, and one which compels admiration.

Passing through some intermediate-houses we found a collection of sturdy *Cattleyas* and *Laelias*, of which the *L. purpurata* and the white and coloured *L. anceps*, were especially good. One mass of *Cattleya Lawrenceana* is the largest and best we have seen of that species; and among the plants of *C. Mendelii* and *C. Trianae* are some with remarkable growths.

In the *Odontoglossum*-house the same standard of excellence was found; but, of course, little bloom. In other houses, *Dendrobium nobile* in variety was found, including *D. n. nobilium*, *D. n. Cooksonii*, *D. n. album*, and *D. n. Sanderianum*, which latter, if true to name and grown well, is a massive and beautiful variety. *D. Venus* ×, *D. Cassiope* ×, and *D. Phalænopsis Schroderianum* are highly spoken of.

We noted among other good things a fine lot of *Cologynes*, a number of plants of well-grown *Calanthes*, principally hybrids, of which some have not yet flowered; *Epidendrum Wallisii*, in flower; and some pans full of pretty *Pleiones*.

The ventilation of the houses has received much study, and Mr. Winn says that it has played an important part in keeping his plants in good condition. A most noteworthy arrangement is the ventilator made use of for affording what is called "bottom ventilation," just above the ground line, and on which so much seems to depend in Orchid culture. All kinds of make-shifts are seen in different establishments, and in all of them, whether of wood, slate, or the sliding iron gratings sometimes seen, it is only a question of time as to when they

become difficult to work or useless. The simple iron traps in use at the Uplands can be regulated easily and to a nicety, and they are practically indestructible. Their adoption generally, would supply a want that is greatly lacking in Orchid-houses as at present fitted.

HINTS ON EXHIBITING CHRYSANTHEMUMS.

Those persons who have not had much experience in exhibiting cut blooms of Chrysanthemums may, perhaps, be glad of a little advice. I find that in the majority of cases cultivators of the flower become desirous, in the course of time, to figure as exhibitors, whether it be the amateur with his two dozen plants, or the gardener with his hundreds; and, nowadays, it is considered to be necessary to count the plants grown for large blooms by the hundred, and in some instances by the thousand. All this is a sign that, in spite of some opinions to the contrary, the cultivation of the Chrysanthemum is increasing.

The aim of the beginner in exhibiting, is to manage his plants in such a manner that each bloom is perfect in its variety, and the latter must be of the best, for it is useless to expect to win prizes with varieties that are inferior, or not up to the present-day standard, no matter what individual fancy or predilection may dictate. As an instance of this, a well-grown bloom of Elaine would not be reckoned superior to an equally well-grown one of Avalanche; neither would a bloom of Barou de Praillet be put as the equal of Vivand Morel; and the same holds good of incurved varieties. A typical specimen of the Rundle section would be quite lost beside a Queen, no matter how perfect the former may be. The larger flower if equalling the other in symmetry must stand first. This method of convincing a beginner of the absolute need of growing only the best varieties in the best manner might be much enlarged upon, but my readers will find the foregoing remarks sufficient for the purpose. As pointed out on p. 460, great care must be exercised in preventing damp injuring the flowers. The blooms as they expand must be constantly watched by day, to make certain that they will be neither too early nor too late for showing at a certain date, as much will depend on their condition as to freshness and development when brought to the show, lack of freshness being, perhaps, the worse condition, costing several points in a competition. If the blooms show signs of being fit too early, the plants must be removed to cooler quarters, and closely shaded from the sun. A dry shed, room, or even the Mushroom-house may be utilised to retard them a little. It is useless to cut any bloom longer than six or eight days, at the outside, before they are required, because they will not keep longer than that; on the contrary, those plants which are not sufficiently forward, must be hastened by a gentle warmth. Want of evenness in a stand of blooms is a defect to be avoided very carefully. By night an exhibitor must keep a look-out for injurious insects, of which there are many species, the worst being the earwig, which secretes itself during the day-time, and feeds on the tender petals by night. Traps made of pieces of Bean-stalks, and pots filled with hay or dry moss, are of great use against the earwig, and the insect should be searched for by lamplight.

The exhibitor of show blooms must be provided with boxes and stand, cups and tubes, the former to hold water, so as to maintain the flowers in fresh condition for several days, the latter to show the blooms off to the best advantage. It is well to have two sizes of the latter for incurved and Japanese blooms alike. There are many ways now of having the tubes made; the best is that which admits of the flower being raised to any desired height without lifting it out of the water. This is the great and a serious objection to many methods now in vogue of making cups and tubes; and those which diminish the water-supply in the slightest degree should not be bought, because the flowers have but a small quantity of water wherewith to keep fresh, on account of the thickness of

the stalk occupying so much of the space in the tube. It may happen that to give proper effect to some one bloom in a stand, it requires to be raised to the full height allowed by the tube, and if the bloom is raised independently of the cup, how can it remain fresh in a heated room for twelve hours, or a longer period? The method which admits of raising both cup and tube at the same time, whether it be the Walker clip or the Jameson spring, matters little, as long as the end in view is gained.

A simple plan, which I adopted a few years since, and which answers very well, is to make clips from common crinoline-steel, half an inch in width; pieces 3 inches long, are cut off, and half-an-inch at one end is bent at a right angle. Four such pieces are required for each hole, they are fastened to the lower side of the stand forming a square round the hole, and being placed in such a manner that when the cup is thrust into the hole in the stand, the four bits of steel clip the cup firmly, either when thrust down to its full depth, or when its end only is inserted. This is a simple method of raising the cups and holding the blooms firm whilst travelling. The pieces of steel are easily fixed with tin-tacks to the stand, or small screws may be used instead. Tubes and cups are made of tin, wood, and zinc; the latter are the best, for they will last a lifetime, and do not rust.

There is some amount of confusion amongst exhibitors as to the names of cups and tubes; some call the article which holds the bloom in position, the cup, from its being cup-shaped, but in reality, this is the tube. I mention this, so that no misunderstanding as to the measurements of each may arise.

As before remarked, the tubes should be made of two sizes—at least, the funnel should be; the stems of each tube ought to be equal in length and diameter, as they should fit nicely into the cup which holds the water. The orthodox size is 2 inches in diameter, and 1 inch deep in the flange; a few of larger size should be provided, as they are useful in displaying large blooms of any kind; these ought to be 3½ inches in diameter, and 1½ inches deep in the flange. The stem should be made 2½ inches long, and of a diameter that will slide into the cup, which is 1 inch in diameter, and 3 or 4 inches long. At the top of each cup there should be a flange one-eighth of an inch broad turned over horizontally. This prevents the cap swaying to and fro when travelling.

Exhibitors should provide themselves with tweezers for dressing the blooms; opinions differ as to which is the best kind, some prefer those made of ivory or bone, but in my opinion those made of steel are the best. The smallest size is 3 inches long and one quarter of an inch wide in the middle; the mouth or points very narrow, just the point rounded off—those are used for finishing off a bloom for exhibition. The next or middle size is 5 inches long, and five-eighths of an inch wide at the rough part in the middle, which is made to allow of a firm grip being had of them, the square points are useful for removing seed-vessels or decayed petals. The largest size is 8 inches long, half an inch wide in the middle, tapering to the points, very useful in regulating the florets of Japanese blooms.

Having explained at some length, perhaps, the necessary appliances with which an exhibitor must be furnished, I will say a few words about the blooms, pointing out the necessary requirements in each section, as a guide to beginners in selecting the competing blooms. At the outset, I would say it is a mistake for any exhibitor—experienced or otherwise—to attempt more than the material at hand will allow in the matter of competition. It is much more creditable to win a first prize in a class for twelve blooms than to enter a class for double that number and to be awarded, perhaps, a third prize. As a guide in selection, I will point out the requirements of each kind of bloom, beginning with the incurved varieties. It is a fault found amongst younger men (and some old ones, too) to imagine that mere size is the one thing to be attained. I grant that size of bloom is the first object a cultivator should have in view, but it must be accompanied by other good points before the bloom will rank as a first-rate specimen. The

three leading points in an incurved bloom are depth, solidity, and colour; and it will generally be noticed that where one of these is present, the others are there also. Solidity is an essential point. An experienced judge knows at once when he sees flowers which are not solid, as the florets do not lay evenly over each other. Although breadth of floret is a point to be aimed at, it should be accompanied with smoothness and regularity, and a trace of coarseness is detrimental. I think, though, that breadth of petal is due more to natural causes, such as the nature of the soil in which the plants are growing, and also to the damp atmosphere in which the cultivator resides. Low-lying districts produce greater breadth in the petals than a higher or dryer one. Blooms of any particular variety—for instance, Empress of India—which are not very broad in the petals, are often more solid than those which have florets of greater breadth, these, through their extra size, not being bedded so closely as are the narrower-petalled ones. The diameter of a dressed representative bloom of the Queen type should not be less than 5 inches, nor its depth less than 3 inches. Blooms are often larger than this, but the size given may be said to indicate a good average specimen. A smaller type of flower is represented by Princess Teck, which possesses much solidity of petal; when in good condition, 4 inches in diameter, and 2½ inches deep, is a good size for this variety. Freshness is a point which carries perhaps more weight than any other with good judges. A want of freshness can be detected at once, and shows itself first round the bottom petals. Good colour should in all varieties receive attention, particularly in the lilacs, pinks, maroons, and bronzes, and the yellows, which should be clear. A dirty white shows a want of freshness, except in caaea where the cultivator resides near a smoky or foggy town.

In the Japanese section the blooms are so variable in form that greater scope is afforded for individual taste in selection. Varieties of the Vivand Morel, A. H. Neve, W. W. Coles, or Avalanche type, are undoubtedly those to be preferred, combining as they do all the qualities of a good bloom without coarseness or thinness; the blooms, when well grown, are large enough in diameter, proportionate in depth, the florets reflexing, with a gentle inclination to droop at the points—in fact, blooms of any of those named can fairly lay claim to being the *beau ideal* of the Japanese race of flowers. A bloom of Avalanche, measuring anything over 7 inches in diameter and 5 inches deep, is good; while the first-named, at 8 inches by 6 inches, is equally so.

Arranging the blooms in the stands next demands attention. That there is a right and a wrong way of doing this is exemplified at almost any show. A common error which tyros fall into, is that of "flopping," as it were, the blooms down on the stands much too low, which is caused by their being cut with much too short a stalk, thus the florets rest on the board itself, and they are dwarfed considerably in appearance. The stem should be cut 1 inch longer than the tube, which will allow for that amount of elevation above the show-board. If the blooms are placed too high in the stands, they have an ungainly look; and there is a certain height at which they look best, and that is when a clear space is shown between the board and the lower florets, no matter how small, in the case of varieties with drooping florets; and where those with horizontal florets are employed, a space at least 2 inches in height should be seen beneath the flowers. In the case of incurved blooms, the back row—generally consisting of the Queen type of bloom—should be elevated 1½ inch above the stand, the middle row a quarter of an inch less, and the front row in the same proportion. Evenness across the top of the blooms is a point which enhances the appearance of a stand; therefore, in the case of extra deep blooms, these figures can only be taken approximately by the beginner. When placing the blooms in the tubes, some exhibitors use pieces of the stem as wedges to tighten the stem of the flower; but I prefer bits of cork cut of a wedge shape. By holding the tube, and the bloom inside of it, in the left-

hand, the cork is easily pushed into the space from below, until the stem is made quite firm. The advantage which the use of cork affords over anything else for this purpose is, that when wet it swells, thus still more tightening the stem, and it is easily drawn out with a pair of tweezers.

In arranging the blooms in the stands, the various forms of the Japanese should be studied; for instance,

PREPARING FOR ANOTHER SEASON.

Long before the present flowering season is past, arrangements have to be made for another. The bulk of early-flowered varieties, of which the Desgranges family are a central figure, will be now past their best. Provision must now be made for providing a stock of cuttings for next year. Cut the flower stems down to within an inch or so of

DOVER HOUSE, ROEHAMPTON.

[SEE SUPPLEMENTARY ILLUSTRATION.]

In July last a visit was made to one of the best kept gardens in the vicinity of the metropolis. Dover House is situate about 2 miles from Putney, on the South-Western Railway, and was the principal residence of the late Mr. Junius Spencer Morgan, the celebrated banker, and although at his death, some two years ago, the place fell to his son (Mr. John Pierpoint Morgan, who resides in America), the gardens have not been allowed to suffer in the least degree, no trouble or expense being spared in their management. Mr. Jas. F. McLeod, who has been head gardener during the last three years, is a thoroughly practical all-round man, who can by no means be described as a specialist, but whose enthusiasm results in an assiduous attention to all the details in every department of the establishment.

The grounds are about 14 acres in extent, and the small portion of these that we can describe as the pleasure ground and flower garden is pretty and attractive. The lawns are exceedingly well kept, whilst the paths, which are of hard gravel, are all that one could wish—not a weed being allowed to show itself upon them.

In front of the white and substantial-looking house is the principal flower garden, which at the time of our visit was looking very gay with Begonias, Pelargoniums, Ageratums, and other summer bedders, besides a small portion of carpet-bedding which was well done and looked very pretty. The design of the flower garden, however, is somewhat too large and intricate for the space at command, and consequently the beds look crowded, and there is too little lawn between them. On the right of the front door is a splendid specimen of the Purple Beech (*Fagus sylvatica purpurea*)—large, handsome, and of symmetrical habit—we doubt if there are many better trees to be seen anywhere.

HOT-HOUSES.

The glass is extensive, and all the houses are in perfect condition. The interior of each is painted every year, which—besides giving to them a good appearance—preserves them to such an extent, that the system is not an expensive one after all. The first house we entered was a lean-to, in two divisions, the first of which is planted with Peaches, from which the fruit had all been gathered. The other—a vinery—was not in a satisfactory condition when Mr. McLeod took charge, and he lifted the whole of the canes, and made an entire new border inside during the winter 1889-90, and the result has been most satisfactory. The varieties are Black Hamburgh and Foster's Seedling, and although bearing a good average crop, the Vines are expected to be as much better next year as they have been this.

The canes in the early vinery have been thrown away, and the borders and drainage renewed. This house is now planted with fine strong canes of Gros Colmar, Mrs. Pince, and Lady Downes', as well as the new varieties, Lady Hutt and Appley Towers—this being now intended as a late-house. The Muscats have been subjected to the same treatment as the Hamburghs, and with equal results. A low half-span, facing due south, with two divisions, is called the Strawberry-house, and here the whole of the 4000 forced plants are fruited. During the summer months it forms a very suitable place for a fine batch of Bonvardias, a number of Celosias, Balsams, &c., relieved with a few Cyperus, and other graceful foliage plants. In the winter it is used for storing some of the Indian Azaleas.

Close to this is another half-span, one half of which had lately been planted with Melons; and here were a few good healthy Gardenias and Ixoras, which Mr. McLeod intends to encourage and increase. The other division contains a batch of Crotons; they are in 5-inch pots, or thereabouts, and are good dwarf, bushy plants. Each of the fifty-six varieties represented have their individual characteristics well developed, and they form one of the most striking features on the place, and are the finest-coloured pieces we have seen this season. Noticeable were

FIG. 85.—NEPENTHES HOOKERIANA: PITCHER, AND PART OF LEAF. (SEE P. 561.)

the drooping character of Boule d'Or should not be altered in such a way as to make it represent a flower with reflexed florets, by too tightly "copping" the blooms. The aim should be to display each form in such a manner as to improve their appearance, if possible, but not to attempt to alter their true character. It is the extreme to which some exhibitors carry this latter that brings Chrysanthemum exhibiting into bad repute with the critics, who are often in antagonism to the principle altogether.

the soil. This section is generally free in producing a quantity of sturdy cuttings, if the plants are not neglected at this time of the year. A cold frame, from which frost is excluded, provides the best place. Here the cuttings grow sturdy, a point to be considered. If too many cuttings grow from the base, and there is a possibility of overcrowding each other to the detriment of all, thin some of the weakest out, thus giving more space to those remaining. *E. Molyneux.*

the new variety *Reedii*, and that useful and pretty *Constadii*, of the Prince of Wales type. Lord Chelmsford, Mrs. Dorman (a variety extensively used for table decoration), *superbus* (which was so highly coloured that the whole plant appeared to be yellow), *Veitchii*, *Aigburthensis*, and *Ilawkeri*; this latter is a very handsome variety when well done, as we saw it here.

It may be worth noting, that the method of propagating *Crotons* practised is that known as the "ringing" process. A ring of bark about one-eighth of an inch wide is taken off the shoot it is wished to strike, and the wound is wrapped with a little moss, which is kept damp. The wound will soon callus, and afterwards the roots come away freely, and when the shoot is taken off, the check is but slight. It is contended that stronger plants are thus obtained than by the common system of striking cuttings.

We next come to a large span-roofed house with two divisions. The first half is used as a show-house, with centre and side stages, which contained many kinds of summer-flowering plants, all gay with their many-coloured blossoms. The roof is partially covered with *Roses*, amongst which is a plant of the beautifully-scented hybrid Tea, *Cheshunt Hybrid*. The other division—the stove—was full of well-grown stove plants of the usual kinds, and the roof supported climbers, such as *Bougainvillea glabra*, *Clerodendron Balfourianum*, *Stephanotis floribunda* (a very free-flowering variety), *Monstera deliciosa* (now bearing fruit), and the pretty *Aristolochia elegans*, with numerous flowers.

Another span-roofed house was occupied by newly-planted *Cucumbers* (*Telegraph*) in the first half, and by fruiting *Melons* in the other. Small fruits with maximum flavour are aimed at, and the varieties in fruit were *Syon House*, *La Favourite*, and *Eastnor Castle*. In the first of these divisions, the early crop of *Tomatoes* had been ripened, the favourite variety being *Sutton's Earliest of All*; but for general crop, *Mr. McLeod* still sticks to *Hackwood Park*.

We then entered a lean-to with north aspect, and one, until the present gardener came, was filled with *Camellias*, but front and back stages have now been put in, and it is filled with *Ferns*, *Caladiums*, *Gloxinias*, &c., with some young plants of the pale blue-flowered *Plumbago capensis* running up the pillars, and bearing a nice quantity of bloom; this is now one of the prettiest houses in the garden.

On the other side of the wall is a long lean-to house with two or three divisions, and in one of these the *Orchids* are accommodated. About three-score of *Cattleyas*, and a goodly number of *Cypripediums* in variety, with a few *Dendrobiums*, are all looking well, and have been got together during the last three years. Another of these divisions is filled with *Peaches*, carrying excellent crops; and in the remaining portion, some *Melons*.

In another part of the establishment, known as the fruit garden, where 3 or 4 acres are entirely devoted to fruit trees and bushes, are two long *Peach-houses*, one about 200 feet in length, and the other (which is a case with a square front) about 150 feet, and faces south-west. In the latter are the latest *Peach trees*, all of which were set with heavy crops of fruit, and the front of the case forms a first-class place for some hundreds of *Tomatoes* grown on the single stem method.

The longer house contained *Peaches* and *Nectarines* on the back walls and upon trellises at the front. In three or four divisions the fruit was in different degrees of maturity. It was astonishing what heavy crops the trees were allowed to carry here, and yet with liberal feeding, good, large, and well-coloured fruits were obtained. An especial favourite with *Mr. McLeod*, is *Princess of Wales*, which ripened a very great number of fruits, each weighing about 9 oz. Other popular varieties in favour here are *Stirling Castle*, *Darwin*, *Bellegarde*, *Grosse Mignonne*, and *Dymond Peaches*. Of *Nectarines*, *Lord Napier* and *Byron* were in evidence. A register has been kept of the number of fruits obtained from each of the trees since they were first planted; and thus if one of them behaves badly, it

is easy to see if its record will warrant further mercy, or whether a visitation of justice in the shape of eviction, will be the proper and most effective measure to pursue. Two other houses are devoted to *Roses* and *Figs* respectively. A great deal of interest is taken in *Carnations*, and the stock of pot and border varieties amounts to 5000 plants. *Chrysanthemums* are done well, and at the time of going to press there are about 1500 well-grown plants commencing to bloom.

FRUIT AND KITCHEN GARDEN.

In the fruit garden, before referred to, *Pears* were a moderate crop, and *Apples* a good average. Small fruits were plentiful, especially *Raspberries*, *Strawberries*, and *Cherries*. The kitchen garden like every other department was the acme of neatness. The brakes and borders are all edged with tiles, and 1 foot from these was a row of *Sweet Peas* round the entire garden. These *Peas* have a very uncommon appearance, and being pinched at the tip when they get about 3 feet high, an enormous quantity of bloom is produced, almost to the ground. Of the pretty and very popular *Princess Beatrice*, there was a wealth of bloom, and no prettier bouquet could be desired than one made exclusively from this *Pea*. Amongst the *Celery* the greatest favourite was *Sutton's White Gem*, which could be blanched in August, and might be had at any time afterwards.

In conclusion, we must not omit to mention a very effective bit of bedding on one of the long *Peach borders*. It was composed of some twelve or fourteen varieties of *Violas* planted in triangular groups, each group containing one variety. The triangles were edged with variegated grass. A row of *Tropaeolums* ran along the back, and the front was edged with *Lobelia*. Nothing could be brighter than were those *Violas*, which were literally covered with bloom. The best of the varieties were *The Mearns*, *True Blue*, *Mrs. Ellis* (the most profuse bloomer), *Wemyss*, a continuous bloomer, and pretty gold variety; and *Archibald Grant*, the largest bloom of all. *Mr. McLeod* strongly recommends this class of plants, and says that all the trouble they have given him has been to take off the seed pods, and bedew the plants each evening. *Viola* cuttings are struck in the autumn at the foot of a wall without any other shelter.

THE WEEK'S WORK.

FRUITS UNDER GLASS.

By J. RIDDELL, Gardener, Castle Howard, York.

POT VINES.—As severe frost may soon be looked for, the pots should be protected; and it will be necessary in the first place to provide each plant with a stout stake, to which the cane should be fastened. Perhaps the general practice of bending the canes until their ends meet, and fastening them then, and also tying the top of the curves to the stakes, is the best to adopt, as any plant can then be removed without having to disturb others. The pots may then be placed side by side in a row, and the canes gently bent till they touch the ends of every fourth cane, and then tied together. Secured in this manner, the canes are not likely to get injured by wind. The pots themselves should be covered with ashes, *Cocoa-fibre* refuse, sawdust, long litter, or litter mixed with tree leaves, so that frost may not reach the roots.

THE ORCHARD HOUSE.—Trees which are standing in pots or tubs should be afforded the same kind of protection to their roots as that advised for the pot Vines, and the pots partially plunged in the soil, thus making them secure against the wind.

STRAWBERRIES IN POTS.—These should be placed in frames, and plunged to the rim of the pot in leaves, litter, &c., taking care whilst doing it not to cover up the leaves of the plants. A lining $1\frac{1}{2}$ foot thick of stable litter may then be placed round the frames. The frames must be freely ventilated, always removing the lights altogether on sunny days, and tilting them when it is

wet; but during severe weather covering with mats, straw, or litter.

MELONS.—Good top and bottom-heat are needed to finish up any fruits that are still unripe, aiming at a minimum of 70° for top-heat, and 10° more for that of the bed, and affording air only in bright sunshine, and then merely sufficient to change the air of the house. Be careful in watering the plants, but still do not let the soil become dry, as it will have a tendency to do owing to the dry atmosphere in the house, and yet not overcharging it with moisture.

THE HARDY FRUIT GARDEN.

By H. MARKHAM, Gardener, Mereworth Castle, Maidstone.

PEACHES AND NECTARINES.—The idea which still prevails that *Peaches* and *Nectarines* cannot be as well grown at the present time, owing to adverse seasons, as was the case in years gone by, may, I think, be put aside as untenable, for if healthy young trees of the right sorts be selected and properly planted, and subsequently treated as they should be in the way of thinning, training, watering at the roots, and repeated syringing to keep the foliage healthy by freeing it from insect pests and dirt, as fine crops of first-rate fruit may be grown now, as at any previous period. For these trees the wall should be built of brick, and of 8 feet to 12 feet in height with a southern or eastern aspect, in places favourable to *Peach* growing. In all cases the wall should have a stone or brick coping projecting from 6 to 8 inches, which forms a slight shelter against frost. The border should, of course, be drained (if the soil is not of a sandy or gravelly kind, when it is seldom necessary), with bricks or stones, and the depth of soil should range from 2 to 3 feet. If the soil is in good heart, very little preparation will be needed, but in stubborn or worn-out soil, much good moderately-heavy pasture loam should be mixed with it; or replace it entirely, adding thereto a good sprinkling of crushed bones, burnt-earth, and a small portion of old plaster or mortar. All these different substances should be thoroughly rammed together when in a moderately dry state, and before the planting of the trees is begun. If crushed bones cannot be obtained, manure should take their place. The border having been thoroughly prepared, the next thing to claim attention will be the selection of varieties. As with other kinds of fruit, all the best varieties of *Peaches* ripen about the same time; but to keep up a lengthy supply of fruit, very early *Peaches* must be included, as well as one or two that are moderately late in ripening. The following varieties will give a long succession:—*Waterloo*, *Hale's Early*, *Early York*, *Early Grosse Mignonne*, *Alexandra Noblesse*, *Stirling Castle*, *Dymond*, *Bellegarde*, *Crimson Galande*, *Barrington*, *Walburton Admirable*, and *Gladstone*. These are good for most purposes, whilst *Alice*, *Condor*, *Royal Charlotte*, *Royal George*, *Old Noblesse*, *Dr. Hogg*, *Goshawk*, and *Sea Eagle* are really good fruits, any of which would not fail to please, and *Princess of Wales* is excellent for later use. The position for the late varieties of *Peaches* should be warm and well drained, or they will not ripen satisfactorily, unless when the season is a very warm one. Of *Nectarines*, *Lord Napier*, *Elruge*, *Stanwick Elruge*, *Pitmaston Orange*, *Violette Hative*, *Pine-apple*, and *Ilumbold*, are all good varieties. The green-skinned *Nectarines*, as *Victoria* and *Albert Victor*, are not to be recommended generally for outdoors, the fruit being much injured by splitting; indoors, however, they are just the reverse, and their flavour is delicious. The distance apart for permanent trees should be about 14 feet, and between these supernumeraries (standards) may be grown for a few seasons. When planting, cut off the tips of any damaged roots, and keep the base of the stem at least 6 inches away from the wall, to allow for growth. The roots should be spread out at different levels, and covered to the depth of 8 inches, trampled firmly and mulched with half-rotted stable manure. Temporary fastenings will be needed to keep the shoots from being broken, but these must be very loose, so that the tree in sinking will not hang in them or be drawn out of the earth. Old fruitless trees should be grubbed up, the soil removed to a depth of two or more feet, and several feet round, and the holes refilled with new soil. Lifting and replanting should only be practised with trees that are barren through rankness of shoots, the main roots having got down to the subsoil, and not from age. For the present, healthy and fruitful trees will

not require attention, unless scale be present, when a good washing with petroleum emulsion, or petroleum at the strength of a wineglassful to a gallon of water, and a little soft-soap, and repeating the washing should the first dressing not prove effectual. Where the trees are very robust and the leaves hang thickly, part may be removed with the hand or a small stick or wisk.

PLANTS AND THEIR CULTURE.

By R. MILNER, Gardener, Penrice Gardens, Swansea.

FORCING PITS.—Where large quantities of cut flowers and flowering plants are required during the winter, much attention must be paid to keeping a due succession of the various plants grown for the purpose. *Azalea indica* is very useful as a winter-bloomer, and may be early forced; but in this event the plants should have been properly prepared by their making timely growth in the spring, which may be pinched back once and then allowed to mature. I never remember seeing this plant in better flowering condition than this season, and the growth is thoroughly matured. Fielder's White, *Deutsche Perle* and *Indica alba* are still the best for early forcing, as are *Azalea amona*, and Carmichael's varieties of *Azaleas*. Lilacs have become very popular flowers, and no wonder, considering how readily they may be induced to flower. The variety, Charles X., is one of the best at this season, and should the gardener find that an insufficient stock is at his command, no time should be lost in buying the required quantity of plants. As fast as the earliest Roman Hyacinths show colour in the buds, remove them to a cooler house for a few days, especially if required for cut blooms, and they will last for a much longer time than otherwise. The same remarks will apply to Paper White and Polyanthus Narcissus. Introduce bulbs and plants into heat in accordance with requirements, and include some pots of early Tulips if the bulbs have made plenty of roots. When Poinsettias are required at an early date, some part of the stock of these plants should be placed in heat. As soon as growth begins, apply weak manure water at intervals. Bring forward a few plants of *Calla aethiopica* and Little Gem, choosing for this time those plants which have been growing in pots, as these are better adapted for forcing than plants lifted from the open ground and potted up at a late part of the season. Put into gentle heat a few plants of *Dieleytra spectabilis* and Solomon's Seal, also *Doronicum*, which are most useful flowers for cutting purposes. If these latter be lifted at once, and placed in a temperature of from 55° to 60°, they may be obtained in flower by the end of the year. See that the stock of plants of *Spiraea japonica* and *S. japonica compacta multiflora*, the last-named being most useful for all purposes, is sufficient for all demands, potting them all as soon as they come to hand, afterwards placing them in a cool house or frame out of the reach of frost.

CHRYSANTHEMUMS.—By the time this Calendar is in print, the chief display of the above will be at its best. In arranging the plants, either make harmonies of like shades of colour, or boldly contrast the colours, and, as a general rule, do not put the modest-looking incurves amongst the larger gaudy Japanese varieties, the latter quite eclipsing them. See that all watering of the plants be done early in the morning, and keep the floors of the house dry, by mopping up the drainage water after each watering. Look over the plants occasionally, removing any decayed leaves and flowers. This is the best time for the amateur grower to inspect some well-grown collection, so that he may decide which he would like to purchase for his own garden, as with the large number of varieties catalogued at the present time, it is an impossibility for those who are not well acquainted with these plants to know which are really the best for any particular purpose or season.

THE ORCHID HOUSES.

By H. A. BURBERRY, Orchid Grower, Highbury, Birmingham.

FLOWERS FOR NOVEMBER.—At one time there were few species which flowered in this month, but fortunately their number is increasing, thanks to the enterprise of collectors and hybridists. We can now enjoy a beautiful succession of flowers the entire year, and that for the present month is not much less in numbers or brilliancy than that which the spring affords. The orchidist who prefers to

have a succession of flowers rather than a glut at one time, and few or none at other times, would do well to make note of the species and varieties which flower each month, and to cultivate such according to his accommodation for them. Many of the *Cypripediums* are in bloom in the autumn and winter, viz., *C. Spicerianum*, *C. insigne* and varieties, *C. longifolium*, *C. Schlimii*, and the many beautiful crosses obtained by the fertilisation of some of these species. Of *Cattleyas* flowering at this season there are *C. labiata* var. the good varieties of which are in point of beauty behind none of the *Cattleyas*; *C. Bowringiana*, another useful and free-flowering subject, with erect trusses of rosy-purple very pretty flowers; *C. pumila* (*marginata*), too, is a species conspicuous just now—it is a lovely flower, deserving of general cultivation. Of the *Odontoglossums* which bloom at this season are *O. grande*, now at its best; *O. Inseleyi splendens*, almost as beautiful; *O. Rossi majus*, *O. Madrense*, and *O. Cervantesii*, also share in beautifying the Orchid-house in this month. Plants of *O. Roezlii*, too, are generally to be seen in flower now as well as in the spring. In *Laelias* we have *L. Dayana*, *L. Dormani-ana*, *L. elegans Schilleriana*, and *L. Perrioi*, the last-named lasts but a short time in perfection. *Oncidium*s show up in great force, viz., *O. varicosum*, *O. Forbesii*, *O. crispum*, *O. tigrinum*, *O. ornithorhynchum*, and *O. incurvum*, which give to the house, if the plants are healthy and of good size, an attractive appearance. Small or weakly *Oncidium* plants should not be allowed to produce a single flower, nor even when they are strong should the flower-spikes be left on the plants for too long a time, exhaustion usually following this practice. *Barkerias* are neither large growers nor very showy plants, but they are pretty, and, therefore, well worthy of a place in most collections. *Barkeria Skinneri*, *B. Lindleyana*, *B. spectabilis*, and *B. elegans* flower in November and later. The lovely pure white and yellow blossoms of *Cymbidium Mastersii* usually appear at this season, and are highly valued. The sweetly-scented *Pleione lagenaria*, an effective plant when well grown and in good bloom; the pans containing the plants should be hung up to the rafters, but low enough to be observed. *Vanda Kimballiana* is a recent addition, and, being possessed of much prettiness, it is a welcome species in the present month. A few *Masdevallias*, too, may always be relied upon to flower if a good collection is grown, and those that are not very beautiful are generally quaint-looking and interesting. *Dendrobium Phalaenopsis*, *D. P. Schroderianum*, *D. bigibbum*, and *D. superbum* are in full beauty in November. The duration of the flowers of these species seems to depend mostly on the clearness of the atmosphere; where the air is murky or there is much cloud, they soon pass over. Lovely, indeed, are they when the whole spike of bloom remains in perfection for a time; that is, when those which first opens keep in good condition till the last is fully expanded. This is easy of accomplishment in the pure air of the country, but rarely in or near smoky towns.

THE FLOWER GARDEN.

By H. W. WARD, Gardener, Longford Castle, Salisbury.

NOISSETTE ROSES.—In continuation of my selection of garden Roses, the following include the best varieties:—*Aimée Vibert*, pure white, small blooms, in clusters; *Celine Forestier*, bright yellow, highly fragrant, and free-growing, the opening buds being good subjects for bouquets, &c.; *Cloth of Gold*, a pale yellow-coloured flower, with centre of a deeper tint, large and vigorous; *Madame Caroline Kuster*, orange-yellow, large and globular, and of vigorous growth; *Madame Massot*, white blooms, in large clusters; *William Allen Richardson*, orange-yellow, flowers small, and best as buds. All the Roses in this and Tea-scented sections give the best effects when they are grown against warm walls, &c., the shoots being low, and about 4 inches apart.

SINGLE ROSES.—Single Roses are decoratively valuable in the flower garden or shrubbery, more especially when planted in masses. The colours of the flowers range from the white of *Rosa rugosa alba* to that of the copper-coloured Austrian Briar, and the blooms are useful for cutting. The following are distinct:—*R. berberifolia Hardyi*, a single yellow Rose, with maroon spot; *Camellia japonica*, a pure white flower, with yellowish stamens; *Copper Austrian Briar*, nankeen-yellow, very distinct; *Macartney Simplex*, large single white, with shining evergreen leaves; *rugosa*, a very handsome species, which

grows about 3 feet in height as a bush, and produces a quantity of carmine-crimson flowers, and bunches of large coral-red berries, that remain on the plant all the winter, if pheasants do not eat them; *rugosa alba* is a white variety of the last-named.

TEA-SCENTED ROSES.—The Teas named in this list have a fairly hardy constitution, and they are free bloomers:—*Belle Lyonnaise*, deep canary-yellow, tinged with salmon, large and full—a seedling from *Gloire de Dijon*; *Catherine Mermet*, delicate flesh-coloured rose—large and full, fine form, and a capital Rose for training under glass roof in a greenhouse; *Comtesse de Nadaillac*, apricot-yellow—a Rose with a globular shape and very double, a vigorous grower; *Devoniensis*, creamy-white, tinted rose—large; *Etoile de Lyon*, sulphur-yellow, with bright yellow centre—large and full; *Gloire de Dijon*, buff, orange centre—very large, fine, strong grower, and a popular Rose; *Letty Coles*, beautiful pink, of good form and free habit; *Madame Falcot*, rich orange-yellow, nice in bud or half-opened; *Maréchal Niel*, the blooms being large, full, globular in shape, and of a deep yellow, and beautifully scented, and the shoots clothed with large shining leaves; *Niphetos*, pale lemon, often white, with beautiful Magnolia-like petals, blooms large and full, very nice in bud. The climbing variety of this Rose, introduced by Messrs. Keynes, Williams & Co., of Salisbury, is admirably adapted for growing under glass or against a warm aspect in southern shires. *Reine Marie Henriette*, is a red *Gloire de Dijon*, and has the good qualities of that favourite Rose.

AYRSHIRE ROSES.—These make compact bushes and are well adapted for planting, either singly on lawns or in shrubbery borders. They bloom freely, and the flowers are small, of white, rose, and other colours. The varieties I prefer are:—*Alice Gray*, *Dundee Rambler* (Myrrh-scented), *Queen of the Belgians*, *Ruga*, very sweet; and *Splendens* (Myrrh-scented).

THE KITCHEN GARDEN.

By G. WYTHES, Gardener, Syon House, Brentford.

FORCED VEGETABLES.—If former directions have been carried out, green vegetables will still be plentiful, but for the sake of variety, others must be forced into growth in sufficient quantity to afford a few choice dishes every week. To obtain forced vegetables of the best quality, there must have been attention paid to their cultivation during the summer. Some roots may be purchaseable, but where large quantities are required they must be grown at home. Seakale roots may now be lifted at short intervals according to the demand for it. That for early forcing should have been grown on a warm border, the roots then forcing readily. If the roots were lifted a month ago, and placed close together in the open ground, covering them with light soil, some of them may be put into heat. In view of the roots forcing more readily when taken out of the soil some few weeks previously to placing them in heat, and of the probability of frost rendering their extraction difficult, a considerable number should be dug up at this season; not forgetting to save all the best thongs for purposes of new stock for planting, which can be finally prepared as cuttings during the winter, laying them in moist earth meanwhile. Seakale is often forced where it grows, the result being good, but this method requires more time, and gives a good deal of trouble. Hard forcing should be avoided in any case, and if the roots are forced in a dark moist place it should not exceed 50° for lifted roots.

ASPARAGUS.—If this should be required towards the end of the year, roots may be lifted, and placed in frames or pits. The shoots are produced in a short space of time, and the longer they are left in the soil the more matured are the buds. One month or six weeks will be sufficient to get it ready for the table. It is a capital plan to make up a good bed of stable dung and fresh tree leaves, and place the roots on the bed when it has reached a declining warmth of 85°, covering the lights at night, and also by day before the shoots grow if the weather be cold. Keep the temperature steady at 50° to 55°. Ventilate a little to allow humidity to escape, and apply fresh dung linings as required if the forcing is carried out in a dung bed.

EDITORIAL NOTICES.

LETTERS FOR PUBLICATION.—All communications intended for publication, as well as specimens and plants for naming, should be addressed to the Editor, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

PLANTS, &c., TO BE NAMED.—Correspondents sending plants or fruits to be named, or asking questions demanding time and research for their solution, must not expect to obtain an answer to their enquiries in the current week. Specimens should be carefully packed and numbered, and not more than six should be sent at one time.

Advertisements should not be sent to the Editor, but to the Publisher.

APPOINTMENTS FOR THE ENSUING WEEK.

SHOWS.

TUESDAY,	Nov. 8	{ National Chrysanthemum, at the Royal Aquarium, Westminster (three days). Chrysanthemum, at Kingston, Enfield, Sevenoaks, and Batley (all two days).
WEDNESDAY,	Nov. 9	{ Chrysanthemum, at Cardiff, Bath, South Shields, Birmingham, Bournemouth, Northampton, and Torquay (all two days).
THURSDAY,	Nov. 10	{ Chrysanthemum, at Birkenhead, Chelmsford, Windsor, Winchester, and Weybridge.
FRIDAY,	Nov. 11	{ Chrysanthemum, at Dundee, Leicester, Wellingborough, Eccles, and Bournemouth (all two days). Also at Hitchin and Pembroke.
SATURDAY,	Nov. 12	—Chrysanthemum, at Exeter.

MEETINGS.

TUESDAY,	Nov. 8	{ National Chrysanthemum, at Royal Aquarium, Westminster.
SATURDAY,	Nov. 12	—Royal Botanic.

SALES.

MONDAY,	Nov. 7	{ Dutch Bulbs, at Protheroe & Morris' Rooms. Greenhouse Plants, Ferns, &c., at Protheroe & Morris' Rooms. Dutch Bulbs, at Stevens' Rooms.
TUESDAY,	Nov. 8	{ Great Sale of Nursery Stock, at Waterer's Nursery, Bagshot, by Protheroe & Morris (three days). Clearance Sale of Nursery Stock, at The Farm Nursery, Stafford, by Protheroe & Morris (two days). Dutch Bulbs at Protheroe & Morris' Rooms. Imported and established Orchids, at Protheroe & Morris' Rooms.
WEDNESDAY,	Nov. 9	—Dutch Bulbs, at Stevens' Rooms.
THURSDAY,	Nov. 10	{ Dutch Bulbs, at Protheroe & Morris' Rooms. Greenhouse Plants, Ferns, &c., at Protheroe & Morris' Rooms. Specimen and other Stove and Greenhouse Plants, at the Alexandra Palace, by Protheroe & Morris. Large Importation of Orchids, and Lilies from Japan, at Stevens' Rooms.
FRIDAY,	Nov. 11	{ Imported Orchids, at Protheroe & Morris' Rooms. Dutch Bulbs at Protheroe & Morris' Rooms. Nursery Stock, at Lee's Nursery Feltham, by Protheroe & Morris.
SATURDAY,	Nov. 12	{ Dutch Bulbs, at Protheroe & Morris, Rooms. Plants, Shrubs, Roses, &c., at Stevens' Rooms.

CORRECTED AVERAGE TEMPERATURE FOR THE ENSUING WEEK, DEDUCED FROM THE OBSERVATIONS OF FORTY-THREE YEARS, AT CHISWICK.—43°·6.

FELLOWS of the Royal Horticultural Society, and those interested in Conifers, will feel that if they have had to wait for the report of the Conifer Conference, they have not waited in vain.* A bulky volume is before us—so bulky, that we can but wonder how the Society can, in addition to other privileges, afford to give to its guinea subscribers a book priced at 15s. 6d.

The
Conifer
Conference.

* Report of the Conifer Conference held at the Chiswick Gardens, October 7 and 8, 1891. Office of the Society, 117, Victoria Street, S.W.

The Conifer Congress last year was, barring the weather, the most brilliantly successful of the many conferences held in the old garden. Never had anything like so magnificent and extensive a display been got together, thanks to the numerous exhibitors in all parts of the country, from the Queen downwards; and thanks also, particularly as regards Scotland, to the zeal of Mr. MALCOLM DUNN. How vast and how complete the exhibition was is indicated by the volume before us, which has been edited with infinite labour and patience by Rev. W. WILKS and Mr. WEATHERS. The Report is a noble contribution to the literature of Conifers, and a very worthy companion to the series of Conference Reports on Orchids, Primroses, Roses, Apples, Pears, Dahlias, Chrysanthemums, Begonias, and others, and to the elaborate Frost Report prepared by Rev. Professor HENSLow for the Scientific Committee. A Society which can command the free labours of such experts, and which does work like this, occupies a very high position, and should receive the grateful support of all interested in horticulture.

A book of nearly 600 pages crammed with information cannot be adequately noticed cursorily. All that we can do at present is to indicate the nature of its contents, and tender the hearty thanks of all interested to the Society, and to all those exhibitors, reporters, and others, who have contributed so zealously to make this work by far the most complete of its kind. After the introductory address, come some papers on the Conifers of Japan by Mr. H. J. VEITCH, Conifers for landscape garden purposes by Mr. NICHOLSON, for economic planting by Mr. A. D. WEBSTER, and for decorative purposes by Mr. BAILEY. Mr. HERRIN of Dropmore Gardens, and Mr. HARDING of Orton, Longueville, give accounts of the famous Pineta under their care. Mr. MALCOLM DUNN follows with an excellent paper on the practical value of various Conifers in all parts of the islands. Dr. SOMERVILLE and Mr. MCKENZIE treat of coniferous timber. Prof. MARSHALL WARD deals with the fungi attacking Conifers—a paper which those who heard it remember as a masterpiece of popular exposition of a very intricate subject. Mr. BLANDFORD then enumerates the insects which are injurious to Conifers. Then follows a systematic list of the Conifers cultivated in Britain, with references to figures, &c., about which all we can say is to express our hope that it will be useful. Professor CARL HANSEN, of Copenhagen, supplies a most elaborate and comprehensive paper on the Conifers of Denmark, and which is, indeed, quite encyclopaedic in its character. Nowhere is there collected together so much interesting information as in this paper of Prof. HANSEN's; and it is satisfactory to find that the scientific arrangement and nomenclature are substantially identical with those adopted in the list of Conifers and Taxads cultivated in great Britain and Ireland. Statistical details relating to the more important Conifers as growing in the several counties are then given, with numerous interesting notes. A list of awards and an index complete a work that will redound to the credit of the old Society for many a long year.

Those who value the privileges afforded to students and artists, of early admission to the Royal Gardens, Kew, will do well to accept Professor FOSTER's suggestion in our last issue, and take immediate steps to safeguard their interests. We believe that no one who can show reasonable cause for admission is refused, if he apply at the

office, whilst regular students are admitted in compliance with the rules, of which we subjoin a copy. Who, then, are excluded till noon? Only the idlers, the nursemaids, and the children. We submit that the interests of this class of the community are already amply provided for elsewhere, and even if they were not, they should not be allowed to prevail against the interests of the garden and of those whose business renders it essential for them to use it for purposes of study.

Probably the greatest amount of inconvenience would be felt by the artists. They can only work when not impeded by visitors; and in the public hours they would themselves constitute an obstruction which could not be tolerated. If, then, a few hours each day are not to be conceded to the artists, their occupation will be gone. Corresponding restrictions would have to be placed upon hotanists and gardeners. It is no time to restrict the scientific work done in this great establishment, rather is it necessary to extend it. The completion of the temperate-house has been delayed beyond all reason. The Orchids, and specially the Nepenthes, require extended and better accommodation. If gardening and maintenance were not well carried out at Kew, there would be little object in asking for further development, but, in point of fact, gardening is so well done as to command the warm approval of the best judges, and to beget confidence that any future additions will be as well cared for as is the existing establishment.

Instead, then, of throwing obstacles in the way of the administration, and instead of subjecting students and others having actual business in the gardens to needless inconvenience, the object of those who value Kew should be to still further extend its usefulness. At one time the general public knew little or nothing of what was done at Kew for the furtherance of the industrial resources of our colonies, though it was well known to experts. The publication of the *Kew Bulletin* has opened the eyes of many to this fact, whilst, moreover, it has made plainer some of the deficiencies of the establishment. A department of vegetable pathology, under the direction of botanical and entomological experts, is a grievous want at the present time, and one that could be readily supplied, to the immense advantage of farmers and gardeners. A department of comparative anatomy, again, is urgently wanted in the interests of science. Systematic botany at present is provided for in the herbarium and library, which are in many respects unrivalled; but they offer relatively little facility for that systematic, comparative, study of minute anatomy and embryology of the living plants which is every day becoming more important from a systematic point of view. It is to be hoped that the appointment of Dr. SCOTT, as Superintendent of the Laboratory, will shortly be followed by substantial progress in this department.

Under the same auspices, researches in vegetable physiology might be made. Some, indeed, have already been conducted in the Jodrell Laboratory, but few in proportion to the needs of science and the requirements of practice.

Garden-botany also demands that the services of three or more trained botanists, equal in rank and capacity to those employed in the herbarium, should be secured, to note and record the plants in the gardens, to draw and preserve such specimens as may be required, to ascertain the correct nomenclature and synonymy, and to be responsible for the adequate labelling of the collections.

Any one of the matters we have referred to

DOVER HOUSE, ROEHAMPTON.

is of infinitely more consequence than the admission of a few nursemaids an hour or two earlier than at present.

We append a copy of the—

“Regulations for the admittance of artists and others in the forenoon:—

“Persons desiring access to the Royal Gardens for the *bonâ fide* purpose of drawing, sketching, photography, or special study, can obtain a card of admission, available during morning hours, on addressing to the Director a written application, stating the object for which such admission is desired. If the application is approved, the card will be sent by post to the applicant's personal address. The privilege of admission is strictly personal to the holder of the card, and it is not transferable.

“A card of admission cannot be issued to admit a class or a party collectively.

“The Gardens may be entered by persons to whom a card is issued, either by the Victoria Gate, opposite the Kew Gardens Railway Station, or by the private gate adjoining the Curator's office. The holder of the card must sign his or her name in the book kept for the purpose at the gatekeeper's lodge.

“Admission may be obtained after 6 A.M. from April to October; after 6.30 A.M. in March and November; and after 7 A.M. in January, February, and December.

“The privilege is not, however, available on Sundays, Christmas Day, Good Friday, or Bank Holidays.

“Persons holding cards may draw, sketch, or photograph in the open air during such hours as the Gardens are open to the public; but drawing in the houses cannot be permitted after noon of each day.

“The Staff of the Royal Gardens accept no responsibility as regards the custody of drawing, photographic, or other apparatus. By Order.

“Royal Gardens, Kew, August 1, 1891.”

NEPENTHES.—One of the most remarkable, if not the most remarkable feature of the exhibition made on Tuesday last at the ordinary committee meetings of the Royal Horticultural Society was the collection of *Nepenthes* shown by Messrs. VEITCH. The plants were of moderate size, but well grown, the pitchers well coloured, and representative of a large number of species, varieties, and hybrids. The display enabled the visitors to see the great variation in form of the pitchers, the deeply-fringed wings of some species, their absence in others, such as *N. Burkei*, the shape of the lids and the curious appendages to them, the range of colour from grey or creamy to glowing crimson, the purple stripes and blotches, the neatly plicate rims of some, the boldly marked ridges of others. We append a list of the specimens exhibited by Messrs. VEITCH, and append a few illustrations. Most of the species have been figured from time to time in our columns, and we hope shortly to give a figure of *N. Northisii* ×, a hybrid between the magnificent *N. Northiana* and the very distinct *N. Curtisii*, and which was shown for the first time on Tuesday last. We reserve a further account of this until our illustration is prepared; but, in the meanwhile, we may point out, lest any should think that a Mr. NORTHIS was commemorated, that the name in question is compounded of those of the two parent plants, *Northiana* and *Curtisii*, *North-isii*. In writing it the sign of hybridity × should never be omitted. The following is a complete list of the *Nepenthes* exhibited by Messrs. VEITCH, November 1, 1892:—

<i>Nepenthes Morganie</i> ×	<i>Nepenthes Veitchii striata</i>
“ <i>Chelsoni</i> ×	“ <i>intermedia</i> ×
“ <i>Wrigleyana</i> ×	“ <i>Domitii</i> ×
“ <i>Burkei</i>	“ <i>Northiana</i>
“ <i>excellens</i>	“ <i>Northisii</i> , new hybrid.
“ <i>Rafflesiana</i>	“ <i>Northiana</i> × <i>Curtisii</i>
“ <i>pallida</i>	“ <i>Curtisii</i> <i>superba</i>
“ <i>Hookeriana</i> ×	“ <i>albo marginata</i>
“ <i>elongata</i>	“ <i>bicalcarata</i>
“ <i>Mastersiana</i> ×, red variety	“ <i>Dicksoniana</i> ×
“ <i>dark variety</i>	“ <i>hirsuta glabrescens</i>
“ <i>sanguinea</i>	“ <i>rubra</i>
“ <i>distillatoria</i>	“ <i>Courtii</i> ×
“ <i>cineta</i>	“ <i>Sedenii</i> ×
“ <i>Veitchii</i>	“ <i>ampullaria vittata</i> major
	“ <i>stenophylla</i>

ROYAL HORTICULTURAL SOCIETY.—The dates of the various exhibitions of the Royal Horticultural Society for 1893 will be as nearly as possible in the following order:—Jan. 17, Feb. 14, March 14 and 28, April 11 and 25, Auricula Show; May 9; Temple Show, May 24 and 25, or 25 and 26; June 13 and 20; July 11, Show at Chiswick; July 25, Carnation Show; Aug. 8 and 22; Sept. 12 and 26 (possibly a great show at the Agricultural Hall, Islington, early in this month); Oct. 10 and 24, Nov. 14 and 28, Dec. 12.

“**HANDBOOK TO THE FLORA OF CEYLON.**”—Under the authority of the Government of Ceylon, Dr. HENRY TRIMEN, F.R.S., Director of the Royal Botanical Gardens in that colony, is engaged in preparing for publication a *Handbook to the Flora of Ceylon*. The work will be illustrated by a hundred coloured plates of the more interesting species. All the known species will be fully described, and much local information afforded, with a view to render the book of use to residents in the island. The first part, accompanied by twenty-five plates, is expected to be ready by the beginning of 1893. The work will be published by Messrs. DULAU & Co., Soho Square, London.

HORTICULTURAL INSTRUCTION.—As this subject is attracting great attention, we print a list of the lectures and exercises for the summer course of 1892 in practical horticulture at the Bussey Institution of Harvard University, Mass.:—July 6: Opening lecture; information in regard to methods of obtaining practical knowledge of gardening in its various forms; books of reference, periodical literature, &c.; examination of the grounds at the Bussey Institution and Arnold Arboretum. July 7: Soils; origin, functions, modifications, and preparation for use; practical work in handling soils for different purposes; examination of natural and prepared soils, and various forms of planting. July 8: Soil, tillage, manures, &c.; exercises in potting and planting. July 11: Propagation of plants; the two general methods and examples of the classes of plants propagated in each way; greenhouse and outdoor work in propagation. July 12: Propagation by seeds in open air and under glass, with lists of plants so handled; practical work as before; systematic inspection of hardy trees and shrubs in the arboretum will now begin, and continue about twice a week during the course. July 13: Propagation by division, layers, stolons, stools, root tips; lists of examples; exercises in these methods. July 14: Propagation by cuttings of the stem; growing and hardened wood, with lists; greenhouse work in making and planting cuttings; construction of the propagating bed. July 15: Propagation by cuttings of the stem; ripened wood in open air and under glass, with lists; work as above. July 18: Propagation by cuttings of the root and root-stock, by leaves and scales, with lists; work as before. July 19: Propagation, grafting (budding and inarching); practical exercises in open air and under glass. July 20: the same. July 21: Cultivation under glass; different forms and classes of plant houses, situation and construction; examination of greenhouses and a large number of plans. July 22: Details of plant growing under glass; soils, potting, training; insects and fungi, practical remedies. July 25: As above; watering and rest; hybridising and selection; practical exercises. July 26: As above; forcing; pits and cellars, cold frames, hot-beds; the frame yard; practical work in preparing and selecting plants for forcing. July 27: Cultivation in the open air; soils, planting, transplanting and cultivating; practical work in this direction so far as the season will permit. July 28: Further details of out-of-door work; pruning, winter and summer; training. July 29: As above; fruit trees and small fruits, with lists of desirable varieties. August 1: As above; vegetables, with lists of suitable varieties for different purposes. August 2: As above; nurseries; various forms of planting;

trees and shrubs for different uses, soils, and situations. August 3: As above; insects and fungi, with remedies in practical use. Supplementary lectures will be given from time to time, taking the place in part of the exercises in the open air, on the more important plants in ordinary cultivation, e.g., Conifers, flowering shrubs, herbaceous plants, Dutch bulbs, garden annuals, house plants, grasses (lawns and meadows), Roses (hardy and tender), Rhododendrons and Azaleas, Plums and Cherries (ornamental), Chrysanthemums, Lilies.

A **NARCISSUS EXHIBITION** is to be held at the Edgbaston Botanical Gardens, Birmingham, on April 26 and 27 next, and prizes in fifteen classes are offered, so that a fine display may be looked for. Five of the classes are for plants in pots for decorative work, Mr. R. SYDENHAM giving £7 10s. in prizes for twelve pots of single, double, or Polyanthus varieties. Schedules can be had on application to Mr. LATHAM, at the gardens.

GARDENERS' ORPHAN FUND.—The committee of the above fund resumed their monthly meetings at the Horticultural Club, Hotel Windsor, on the 28th ult., Mr. B. WYNNE in the chair, in the absence of Mr. W. MARSHALL through indisposition. The minutes of the last meeting having been read, the chairman announced that 10,200 collecting cards had been sent out with a view of taking the national collection, all of which were returnable by November 1. Of those returned the average sum was quite up to last year. The following special receipts were announced:—Mr. and Mrs. HARRY J. VEITCH, as a thankoffering on the celebration of their silver wedding, £250 each, conditionally upon its being invested. A very hearty vote of thanks, coupled with expressions of the best wishes of the committee, was given to Mr. and Mrs. Veitch; the Wimbledon Horticultural Society, £6 6s.; Mr. H. J. Clayton, Grimston Park Gardens, Tadcaster, £6; Beddington Flower Show, per Mr. G. W. Cummins, £5; Burton-on-Trent Horticultural Society, £2 2s.; Mr. Bowerman, Hackwood Park Gardens, 10s.; The Walkley Amateur Horticultural Society, per Mr. E. Smith, £1 10s.; Mr. W. Dennington, Hampton, 10s.; Mr. J. Miller, Ruxley Lodge, Esher, 21s.; Mr. J. B. Stevenson, Bournemouth, 12s. 9d.; Mr. J. Hamilton, Byrkley Gardens, 15s.; Mr. R. Dean's sale of flowers at the Royal Aquarium, £2 15s. 3d.; and money-boxes, Mr. J. Atherton, Preston, £1 10s.; and Messrs. Sutton & Sons' box in their shop at Reading, £1 11s. 6d. The secretary announced the recent death of Mr. C. H. Sharman, a member of the committee, and one of the earliest workers on behalf of the fund. A vote of condolence with Mrs. Sharman was carried, and the secretary was instructed to convey the same to her. Mr. Robert Ballantine, the chairman of the National Chrysanthemum Society was elected a member of the committee in the place of Mr. Sharman. The secretary was instructed to make arrangements for the purchase of £500 worth of consols.

BRITISH MOSSES.—Lord Justice FRY has published in book form (WITHERBY & Co., 326, High Holborn), the very comprehensive account of mosses in general which he originally gave as a lecture at the Royal Institution. It is the simplest and clearest account (consistent with accuracy) of the structure and mode of life of mosses that we have met with. The formation of peat bogs, and the curious changes which peat undergoes, and which converts it from a highly absorbent substance to one impervious to water, are treated of in connection with the successive appearance and disappearance of superposed forests. “To the intimate structure of the Turf Moss are thus to be attributed great results in the history of the world. To look at our own island alone: but for it, the primeval forests that once covered the land might still be standing; but for it, large tracts of land would still be lake and mere; but for it, every freshet in a highland river would be a flood; without it, we should have had no

mosses on the confines of England and Scotland, and where would have been the border warfare and the border minstrelsy? Where the moss hags in which the hunted Covenanters sought for shelter and freedom of worship? To come southward, by force of its growth, the broad meadows of Somerset have been built up, and the dark waters on which the mysterious barge bore the dead ARTHUR from Tintagel to Avalon have been turned into the green pastures of Glastonbury and Meare, and the battlefield of Sedgemoor."

"COCOA: ALL ABOUT IT."—Messrs. SAMPSON, LOW, MARSTON, & Co. publish a little work under a title so comprehensive that nothing remains for the reviewer to add. History, cultivation, analysis, and manufacture are all treated of, and illustrated by numerous rather coarsely-executed illustrations, some of which are very quaint. The botanical details, typographical and illustrative, are rather defective, and the same remark may be made as to the Vanilla. It will be news to some of our readers to know that coniferin, a principle occurring in Conifers, may be so treated as to yield vanillin, the aromatic principle of the Vanilla pods. Coniferin, we are told, has in consequence been collected by hundreds of kilogrammes in the forests of northern Germany. Our forest proprietors in Scotland should take note of this.

"A TEXT-BOOK OF AGRICULTURAL ENTOMOLOGY, ETC."—Messrs. SIMPKIN, MARSHALL & Co. have published under this title the second edition of an excellent book by Miss ORMEROD, and which under the clumsy title of a *Guide to the Methods of Insect-Life* did not, as we are told, make much way in spite of its merits. The establishment of county councils and technical education classes, however, created a demand for the book, which is accordingly reissued in an extended form and under a more appropriate designation. We cannot doubt that the great utility of the book will now be duly recognised.

WINCHESTER AND DISTRICT GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.—At the fortnightly meeting of the above society, which took place on the 27th ult., Mr. E. MOLYNEUX, Swanmore Gardens, Bishop's Waltham, read an instructive paper on "The Apple" to an appreciative audience, giving practical illustrations on pruning and other topics. A capital collection of Apples was contributed by members of the association, the largest, consisting of thirty dishes, coming from Mr. G. MALDOW, gardener to Miss TURNOUR, Kingsworthy House.

SETS OF BRITISH RUBI.—As already announced in the *Journal of Botany*, the Revs. E. F. and W. R. LINTON, R. P. MURRAY, and W. MOYLE ROGERS propose issuing a limited number of Sets of British Brambles. Each set will consist of four fascicles. The British list of Rubi may be said to consist of about 100 "species." The compilers hope to include in the set nearly all the rare and local plants, as fully authenticated as possible. As, consequently, much time must be consumed and expense incurred in getting the material together, the several fascicles will be issued at intervals of about a year; a plan which, it is hoped, will also prove convenient to the subscribers. Each fascicle will contain twenty-five full sheets, representing as many different Brambles. A few well-marked varieties will be introduced, but no hybrids. The price of each fascicle will be one guinea. Subscribers to the first will not be considered bound to take any of the succeeding fascicles; but will be expected to inform the compilers within three months of the receipt of a fascicle whether they intend to subscribe for the next. Communications should be sent to the Rev. E. F. LINTON, Crymlyn, Bournemouth.

MR. KRELAGE'S LIBRARY.—The *Bookworm* for the present month contains an interesting article on the famous botanico-horticultural library accumulated at Haarlem by Mr. KRELAGE, and which has often been the subject of comment in our columns.

ERRATIC ORCHIDS.—Mr. COCKBURN, of Milton Bridge, sends us a photograph of *Cypripedium barbatum*, the flower-stalk of which bears, in addition to the flower, a small, well-developed leaf, bearing a leaf-bud in the axil. A second photograph of *C. Chamberlainianum* shows a fully-developed flower, a flower-bud, and from the pedicel bearing the latter, a leaf-bud in the shape of a *Cypripedium* plant in miniature. From Mr. O'Brien we have a flower of *Cypripedium Spicerianum*, in which the two lateral sepals are turned downwards and connate. There is but one petal, and that is median, in the position where the upper sepal, here absent, is normally found. The lip was also absent, but in the centre of the flower a column with two staminodes, one anterior one posterior, and two perfect lateral stamens in the ordinary position. There was no trace of ovary or style. From the same source we have received a flower of *C. Lawrenceanum*, with two connate lateral sepals directed downwards, the petal median and posterior, in the place of the missing posterior sepal. The lip is opposite this petal. In the centre is the column, with two perfect anthers not placed laterally as usually in *Cypripedium*, but one in front and one at the back, thus alternating with the two petals. On each side of the column is a two-lobed staminode.

"CONTRIBUTIONS TO HORTICULTURAL LITERATURE."—Her Majesty the QUEEN has accepted from the author, Mr. WM. PAUL of Waltham Cross, a copy of his newly-published volume, *Contributions to Horticultural Literature*.

WEIGHTS AND MEASURES.—At the annual meeting of the American Seed Trade Association, held at Hartford, Conn., June 16, a committee on weights and measures was appointed and its special duty named (according to the *American Florist*), as the consideration of the Cental System (making all quotations per 100 lb. instead of per bushel), in all sales of seeds, and instructed to formulate some plan for united action in the matter. After careful consideration, and consultation with some of the leading houses in the trade, who have without exception favoured it, we now recommend that said system be adopted in buying and selling Clover, Timothy, Blue Grass, Orchard Grass, Red Top, Lawn Grass, Millet, Hungarian, and all kinds of grass seeds; also Buckwheat, Cane, Broomcorn, Sunflower, Osage, Hemp, Castor Beans and Pumpkin Seed, and we most earnestly request that all seedsmen and dealers in the United States and Canada, adopt this system beginning January 1, 1893. And use the same in preparing all catalogues and other printed matter to be issued on or about that date for the spring trade of 1893, and thereafter. The advantages to be gained are manifold: The legislatures in the various States have established "legal weights," stating number of pounds which shall constitute a bushel, and these vary so greatly, that much controversy is caused in interstate commerce, which cannot occur under the Cental plan. This change will also save considerable labour in receiving, shipping, and billing out goods, and do away with a large proportion of the vexatious and costly errors which often occur under the old plan. We suggest and recommend that Clover, Blue-grass, Red-top, orchard-grass, &c., be quoted by the pound; while Timothy, Millet, Hungarian, Buckwheat, and the lower-priced seeds, be quoted by the 100 pounds. At this time we do not recommend that the change include Peas, Beans, Corn, Flax, Wheat, Oats, Rye, and Barley, but from present outlook we believe that it is only a question of time when we can include them all."

BRAZILIAN EXHIBITION.—Viscount SAINT LEGER has established in Paris a permanent exhibition of Orchids and other Brazilian products.

THE LATE MR. E. COOPER.—A committee, which consisted of the personal friends of the late Mr. E. COOPER, who was for so many years gardener to the Right Hon. JOSEPH CHAMBERLAIN, M.P., at Highbury, have succeeded in obtaining a sum of

money for his widow amounting to £58. This sum has been handed to Mrs. COOPER, who desires that her sincere thanks should be communicated to those who have so kindly helped her in her trouble.

TECHNICAL EDUCATION IN HORTICULTURE.—We learn that Mr. A. M. C. JONGKINDT CONINCK, formerly of the Nurseries at Dedemsvaart, Holland, will carry on a technical school for affording instruction in horticulture. The school was opened for the reception of pupils on November 1. Mr. CONINCK, who spent some time in this country, is quite competent to carry out the work he has undertaken.

ROYAL HORTICULTURAL SOCIETY OF ABERDEEN.—The annual meeting of the above Society was held in the Music Hall buildings, Aberdeen, on Saturday evening, the 29th ult. Lieut.-Colonel CROMBIE presided, and there was a large attendance. The Chairman, in submitting the annual report, said that the financial surplus on the year amounted to £435 18s. 9d., which, added to the balance brought forward from last year, made the sum of £696 3s. 7d. at the credit of the Society. He formally moved the adoption of the report.

WINDOW GARDENING IN LONDON.—We learn from the *Leisure Hour* for November that Lord LEIGH, Lord-Lieutenant of Warwickshire, in a speech at Kenilworth lately, gave a fragment of his personal experience of window gardening in London. At the beginning of the Queen's reign, flower shows, with the exception of the annual flower *fête* at the gardens of the Royal Horticultural Society at Chiswick, were rarely held, and flowers were seldom seen in the houses or on the window-sills of the poor in London. Nowadays exhibitions are everywhere arranged, and one may go from Belgravia to Bow, and from Westminster to Whitechapel, and everywhere see the cultivation of plants, and witness the love of flowers.

PRESENTATION.—On Thursday, October 27, the friends of Mr. ANGUS McLEOD, until recently head gardener at Headfort Gardens, Kells, co. Meath, presented him with an address, accompanied by a purse of gold, on his resigning his post at Headfort. Mr. McLEOD was head at Headfort for more than six years, during which time the great interest he took in the promotion of Irish horticulture, together with his genial manners, won him many friends. His name figured as a prizetaker at most of the Dublin, and at many local shows.

YOUNG GARDENERS AND FRENCH RESIDENCE.—Young men wishing to improve their gardening knowledge by making a stay in France, can obtain information at the seat of the London French Horticultural Society, 27, Gerrard Street, W., on the first Saturday of each month, at 8 P.M.

APPLES ON PEAR TREES.—Rev. Canon WALSHAW is answerable for the following statement, communicated to the *Sheffield Daily Telegraph*:—"The finest Ribstons that I have seen and tasted grew upon a noble Pear tree, where the Apples of the richest tiuts hung intermingled with Pears, both of Jargonelle and Marie Louise variety. The parent-tree, the Jargonelle, had been grafted with shoots of the Marie Louise Pear, and of Ribston and Golden Pippin Apple trees. The Ribston proved the most successful in fruit-bearing, the Apples so perfect in shape, and so rich and delicate in colour, as to resemble the finest-tinted specimens in wax or porcelain; while for the table the fruit was rich with the melting juiciness of the Jargonelle, combined with the aromatic flavour of the Ribston. While often admiring the abundance and beauty of the laden branches of my friend's favourite tree, its owner would repeat the story of his horticultural triumph, for he had been assured by a high-class and scientific gardener that his attempt to raise Apples on a Pear tree was contrary to nature, and must end in failure. Following my friend's example, I in like manner succeeded, and should have been happy to have offered to a friend a Pippin of my own grafting

in the days of my residence on the banks of the Tees, among the fair scenes which Sir Walter Scott has so faithfully described in his *Rokeby*. I may further note, that a basket of choice Ribstons was sent from the tree spoken of to the Duke of Cleveland of above thirty years ago. The fruit adorned the dessert-table of a large company at Raby Castle, and was pronounced by all not only fair to the eye, but most delicious in flavour. In venturing to send these lines I am induced to express a hope that in these days, when improvement of fruit culture in our country is so desirable, the experiment may be extended, and that both connoisseurs and others may not only be rewarded by rich and fair fruit for the table, but that baskets of the same may appear in the markets not without profit to the grower. The

It frequents dry slopes, generally on lime or sandstone, and is described as a low, round-topped tree, not exceeding 30 feet in height, branching from the base, and yielding a soft wood, useful for fuel or fencing purposes, but of little worth for building. The seeds which, like those of the Swiss *P. cembra*, are destitute of wings, are collected by the Indians, to whom under the name of Piñon, they constitute a valuable article of food. In this country, we have noted the tree at Pampesford, Kew, and elsewhere.

The buds are cylindrical-oblong obtuse, covered with light brown deltoid acuminate scales. The herbaceous shoots are greenish, glaucescent, cylindrical or somewhat three-sided, and slightly setose, generally completely clothed with leaf-tufts, but sometimes naked at the base. The leaves are in pairs or

projecting ends (apophysis) prominently four to five-sided, with a lozenge-shaped boss or umbo of a lighter colour, and a small mucro, both directed downwards. The seeds, 12 to 15 mm. long, are egg-shaped, somewhat flattened, brownish, and entirely destitute of wing. As they become dry, the scales of the cone separate widely, give a very different appearance to the cone, and leave the conspicuous egg-like seeds exposed.

Engelmann remarks that the species *P. monophylla*, *P. cembroides*, and *P. Parryana* (he might have added *latisquama*), form a group with the leaves of the flexilis group, the seeds of *P. cembra*, and the cone and scales of *P. Pinaster*. All these have very short leaf-sheaths, with recurving perulae, and the leaf-structure is essentially the same in all. It is evident also that there is some close affinity with the Chinese *P. Bungeana*.

From *P. monophylla* the acuminate, not obtuse, bud-scales and more slender leaves furnish a distinction. From *P. cembroides* (the *P. Llaveana* of Pinetum Woburnense), the present species (*edulis*) differs in its shorter, thicker leaves, which are stomatiferous on the dorsal side, and oblong, not globose, cones. The boss of the scales is also more markedly deflexed.

All the Pines now mentioned belong to the group of "Nut Pines," so called on account of their edible seeds. It has been suggested that they are all forms of, or at least derivatives from, one species, and this is by no means unlikely; but inasmuch as they can mostly be distinguished without much difficulty, and the anatomical characteristics, though essentially the same, differ in points of detail, it is as well to keep the forms distinct, pending the acquisition of fuller knowledge. *M. T. M.*

BOOK NOTICE.

TRAVELS AMONGST THE GREAT ANDES OF THE EQUATOR. By Edward Whymper. Second edition. (John Murray, 1892.)

We have been tardy in calling the attention of our readers to this book, but not so tardy by a long way as the author was in publishing it, for more than ten years elapsed between the conclusion of the journey and the appearance of the book. It is the record of an adventurous journey undertaken by Mr. Whymper (whose prowess as an alpine climber is well-known) amongst the mountains of Ecuador. He was accompanied by two trusty Swiss mountaineers, and the whole journey, including ascents of Chimborazo (20,000 feet), Corazon, Cotopaxi, Antisana, Pichincha, and other giants, was successfully accomplished. The book is well printed, beautifully and usefully illustrated, and generally well got up. Mr. Whymper's main object was to determine whether human life could be satisfactorily maintained at lofty elevations, and, if not, to ascertain what were the precise conditions which produce the evil results. Mountain sickness is shown to depend, first, on diminished atmospheric pressure, which lessens the value of the air that can be inspired at any given time, which induces suffocation in the same way that an insufficient supply of air would do; and secondly and concurrently, by causing the gas or air within the body to expand and press upon the internal organs. In the course of his travels, many subjects, directly and indirectly, attracted the author's attention. The topography and natural history of the country, the manners and customs of the people, prehistoric antiquities may be mentioned as among them, and as likely to interest many more than will be concerned with the effects of diminished pressure at such elevations either on human beings, or on aneroid barometers. We proceed to note some of the observations which may have special interest for our readers, premising that they will find the whole book well worth reading for the abundant information it contains. A lichen (*Lecanora subfusca*) braves diminished pressure at a height of 18,500 feet on Chimborazo.

FIG. 86.—PINUS EDULIS: FOLIAGE, CONES, AND SEED.

Golden Pippin seems now to have deteriorated. I would recommend the experiment to be tried with grafts also from the Alexandra or any other handsome and well-flavoured Pippin.—I am, yours most sincerely, S. CANON WALSHAW, October 17."

PINUS EDULIS.*

We are indebted to our excellent colleague, Professor Meehan, for the opportunity of figuring the cones of *Pinus edulis*, a species grown in this country, but which has not, so far as we know, produced fruit here. It is an interesting species, extending, according to Sargent, from the eastern base of Pike's Peak, Colorado, where it ascends as high as 9000 feet, to New Mexico and the mountains of Western Texas.

* *Pinus edulis*, Engelmann, in *Wishizenus' Report*, p. 4; Parlatores, in *De C. Prod.*, xvi. 2, 398; Sargent, *Report on Forests of N. America*, No. (1854), p. 190; Coulter, *Botany of Rocky Mountain Region* (1885), p. 432; Coulter and Rose, *Botanical Gazette* (1886), p. 303—leaf anatomy. Syn. *P. cembroides*, Gordon, in *Journ. Hort. Soc.*, p. 238.

in threes, closely approximate and tardy to separate one from the other. The leaf-tufts are surrounded at the base by a very short sheath, consisting of short recurved lanceolate brown scales. The individual leaves are ascending, arcuately curved, 1½ inch (4 cm.) long, pale ashy-green, linear, sharply pointed, entire or very obscurely serrulate, convex on the dorsal side, with numerous shallow furrows beset with stomata, concave on the upper side, with two to three broad bands of stomata on either side of the midrib. The transverse section of the leaf shows a semicircular or triangular outline, with stomates on all surfaces, a thick layer of hypoderm, two resin-canals close to the epidermis, and surrounded by strengthening cells; the fibro-vascular bundles circular and single. The male catkins are in racemose clusters, each cylindrical-oblong, yellow on anther-crest, thick and wavy. The cones are nearly sessile, in whorls of three in our specimen, each spreading nearly horizontally, and about 2 inches (5 cm.) long, 1½ inch (4 cm.) wide, ovate-oblong. The scales are woody, of a light brown colour, their

On the slopes of Chimborazo also, Mr. Whymper tells us, they, the explorers "found a *Calceolaria* (*C. rosmarinifolia*, Lam.) in abundance near Chuqui-poquo; and several species of *Gentiana*, of *Lupinus* and *Cerastium*, a *Valeriana*, a *Vaccinium*, and a *Ranunculus* (*R. peruvianus*, Pers.), growing between 12,000 and 14,000 feet. The grasses upon the slopes were principally *Poas*, *Fescues*, and *Deyeuxias*. When about 13,800 feet high, we caught sight of a large white spot about a mile off, and found it was an isolated patch of a splendid grass (*Gynerium argenteum*, Nees) growing 8 to 9 feet high, by the side of a little stream. A few days later, we discovered the same species 2000 feet lower, near Mocha, but these were the only localities where it was noticed. A little below 14,000 feet, on the north-east side of the mountain, at the foot of some cliffs, facing the north, I was attracted from a long distance by the flowers of some Currant-bushes (*Ribes glandulosum*, R. & P.). This is the greatest elevation at which an example of that order was obtained in Ecuador."

On the summit of Carihuairazo Mr. Whymper found other Cryptogams, as mentioned in the following paragraph—

"Our peak terminated in a snow-cone too small to stand upon, with a little patch of rock peeping out a short distance down upon the north side, bearing some lichens (*Leciden* and *Lecanora*), and, for such a situation, a not inconsiderable quantity of a moss which has been dubiously identified as *Grimmia apocarpa*, Hedw. This same species was found in the previous January near the second camp on Chimborazo, at the rather exceptional height (for a moss) of 16,600 feet; but it was more remarkable to find it on the very apex of Carihuairazo (16,515 feet), completely surrounded as it was by permanent snow and ice upon all sides, as truly insulated as if it had been upon an island surrounded with water."

Speaking of his botanical collections, as a whole, Mr. Whymper writes—

"The collections which were formed were undertaken with the view of contributing to the knowledge of the range in altitude of species, and the remarks which follow have solely reference to the extreme upper range of species in Equatorial South America. Examples of twenty botanical orders were obtained at 15,000 feet above the level of the sea, and upwards, and twelve of these touched or exceeded the height of 16,000 feet. In the tables upon pp. 352, 353 the altitudes are given, and the names of the species, so far as they have been identified, of the representatives which attained the very greatest heights. These tables, and the zoological ones which follow, include only such species as were actually collected.

"Species of fifteen genera of lichens were collected in the interior of Ecuador, out of which eight were obtained at 15,000 feet, or higher; examples of twenty-six genera of mosses were collected, twelve of which were found at 15,000 feet and upwards; while out of fifty-eight genera of flowering plants (collected exclusively in the interior) fifty-nine species came from 14,000 feet, or higher, and of these, thirty-five species reached or surpassed 15,000 feet, and twenty species 16,000 feet, above the level of the sea. Including all orders, forty-two species were taken at 16,000 feet, or higher,* and almost all of these came either from Antisana or Chimborazo,† principally from the latter mountain,

* So far as I am aware, nothing has hitherto been obtained from the height of 16,000 feet in Equatorial America, except the lichens mentioned in the note at the foot of p. 334, and perhaps the moss to which reference is made at p. 76. The Saxifrage, which was discovered by Boussingault upon his attempt to ascend Chimborazo in 1831, Humboldt says (*Aspects of Nature*, vol. ii., pp. 35, 36), was found at 15,770 feet. "On the declivity of the Chimborazo, the Saxifrage Boussingaulti, described by Adolph Brongniart, grows beyond the limit of perpetual snow on loose boulders of rocks at 15,770 feet above the level of the sea, not at 17,000 feet as stated in two estimable English journals. The Saxifrage discovered by Boussingault is certainly, up to the present time, the highest known phenogamous plant on the surface of the earth."

† These will be found enumerated upon pages 199 and 333-4.

which even at the height of 17,000 feet has a large amount of soil free from snow. One looks vainly amongst this flora for the brilliant clusters of gem-like flowers which are so conspicuous near the snow-line of the Alps. Yellows predominate in it, and they, like the other hues, are wanting in purity. The highest species, with few exceptions, were also found at considerably lower levels; and the plants which were taken at the greatest altitudes were generally solitary individuals, separated by long distances from their nearest relatives."

It will be seen that Mr. Whymper paid relatively little attention to the natural history below an elevation of 14,000 feet, and, therefore, we find little or no mention of Orchids, Tacsonias, Melastomads, and other beautiful plants of that region. Mr. Whymper's researches, however, may be supplemented by reference to the works of Dr. Jameson, André, and other recent travellers, to say nothing of Humboldt and Boussingault. To those who wish to learn something about the glaciers of the Andes, the volcanos active and passive, the volumes of volcanic dust, the pumas, the condors, and the numerous other matters touched on by Mr. Whymper, we must refer the reader to the book itself. It is a volume which will not only be read, but placed on the shelf for future reference.

HOME CORRESPONDENCE.

LANDSCAPE GARDENING (p. 493).—Kindly let me say that the statement in your review that I "would bring the field up to the house-wall without any intervention of formal feature at all," does not represent either my views or acts. On the contrary, I am often putting beautiful flowers before the house-wall, and adorning the necessary formality thereabouts. In many cases, the best foreground for a house is a beautiful flower-garden, cut off as it must be with a low wall from the field or park near. Even if one wanted to do so, it would not be easy to bring the field up the red crag of Powis Castle or Berkeley. Where in large places the flower-garden, often through a reaction from bedding-out, is turfed over, nothing is more unwelcome to me than to see only grass where flowers should be; and that in places where there are many acres of ground around and within view. Turfing what ought to be a fine flower garden has unfortunately been done at many places of late years, of which Losely Park is an instance. But in many gardens in the Thames valley, and elsewhere in the rich lowlands, where land is valuable, and, for many owners gardens are limited in area, it is often far the best way to have a lawn directly in front of the house for the sake of its verdure and repose. Examples of this may be seen in Mr. Martin Smith's garden at Hayes Common, at Bristol House, Roehampton, at Greenlands, and many other gardens. *W. Robinson.*

PACKING FLOWERS IN DEAL BOXES.—Noticing the paragraph on p. 532 of the *Gardeners' Chronicle*, I may say that when at Lillieshall, the Duke of Sutherland's Shropshire seat, in 1870 and 1871, Mr. Elliot, the Duke's gardener, always had the bouquet boxes (deal) soaked in water when flowers had to be sent to the late Duchess, and more than once she expressed her gratification with the freshness of the flowers after a long journey in hot weather. *J. Udale.*

DUPPLIN.—In the description on p. 525, "M. T." makes hardly any reference to the grounds and park at Dupplin. As I have visited the place nearly half-a-dozen times, and had many a pleasant chat with the courteous gardener, Mr. Browning, perhaps "M. T." will not mind a cursory mention of one or two out of the many beautiful and impressive features of the policies and park. First, a word as to the splendid position of the kitchen garden. From a sheltering wood a steep slope descends to a wide bend of the Earn, where the river forms a deep salmon pool and a tree-covered islet. The only garden in Scotland that I have seen on a gradient of the same angle is at Blair Athole, but there is only a curling pond there instead of the river. The steepness does not seem to make any difference in the geotropic influence, though it must do so on the crural sinews and muscles of the workmen in the garden. The walk to the castle from the kitchen garden, with its view over the country to the blue Ochil hills, is lined with sombre Yews, with Douglas Firs,

heavily layered with branches, at intervals. There can be no doubt as to what claims description near the house. It is "the dell," which is quite close, only the flower garden intervening. The dell, as it is called, is a fairly-deep glen cut by a stream; the sides are planted thick with *Rhododendrons*, *Laurels*, and other shrubs. At the head the stream issues out of the greenery, and dives over a rocky ledge, forming a waterfall, and bustles quickly down to where the sides of the glen are lined with young trees. Every means have been taken to develop the natural beauty, so that it really seems nothing more could be done to increase the loveliness of the scene. How much preferable than any formal garden must be the thought of all with any aesthetic taste who have been privileged to see "the dell." The main approach from the pretty village of Aberdogie is by a fine avenue, passing through what is called the Hexagon, where vestas open out in all directions. The park is very extensive, and has all the characteristics of a great English park. The woods on the estate, too, stretch for miles, and there is a large reservoir for trout-breeding. To the lover of Scotch history, the place is interesting as being the home of one branch of the Hay family. The legend of the traditional founder of the family is so strange that I will give it as concisely as I can. Kenneth III., King of Scotland, had to march with an army hastily raised to meet the Danes, who were coming up the Tay. After an obstinate bloody battle, the Scots broke and fled. While retreating down a narrow pass, they were met by a peasant named Hay and his two sons, armed with oxen-yokes, who stemmed the flight and led them back, and turned a defeat into a victory. After the battle (970 is the supposed date) Kenneth offered the valiant Hay "as much land as a falcon could fly over without perching." Modern historians, of course, say there was no such battle, but Dupplin is a solid proof within the required distance. The second Earl of Kinnoul fled with Montrrose, but died from the exposure, and thus saved his head. *Fagabond.*

MANURES FOR STRAWBERRIES.—I would advise "New Subscriber" to apply a top-dressing of guano, one ounce per square yard, in order to encourage root development during the winter, and then as soon as the weather will permit in the early spring months, to apply another dressing of guano in the same proportion, following this up by pretty frequent applications of liquid manure. That obtained from horse-stables being the best; or an old bag may be filled with sheep-droppings and soot, which can be thrown into a tub of water, when most efficient liquid-manure will be obtained. In America, early Strawberries are sometimes forced by the application of nitrate of soda applied as a top-dressing as soon as weather permits and the growing season begins; but it is probable that in England this would cause a too vigorous growth of leaf, instead of maturation and fruiting. *J. J. Willis, Harpenden.*

WIREWORMS.—The ravages in garden crops caused by wireworms are so common, and the sufferers constantly on the watch for something that will free the land from them, I have been induced to look up some references to the subject in a standard work. John Curtis, in his *Farm Insects*, mentions the fact, on the authority of Dr. Roy, "that on breaking up damp meadow and pasture-land in Lincolnshire, if it be sown with Woad instead of corn, the wireworm will be got rid of, and about Boston it is found to be a very profitable crop. It may be repeated for two years, after which splendid crops of Oats and Potatoes may be obtained from the land. It may not be irrelevant to remark here, that it is a prevailing opinion respecting the Bedford Level that over-draining has caused great mischief to the Wheat crops by increasing the wireworms." The same writer also states that White Mustard seed sown on land will secure the succeeding crop of Wheat or other corn against this insect, and an instance is given where a farmer tried an experiment on half an acre in the centre of a 50-acre field of fallow, which was subject to the wireworm. The Mustard being carried, the whole field was fallowed for Wheat, and the half-acre that had been sown with White Mustard was wholly exempt from the wireworm; the remainder of the field was much injured. Encouraged by the results, he, in the course of a year or two, sowed 42 acres of this field with White Mustard, and not a single wireworm could be found the following year. It was thought that the wireworm, not finding any other roots in the soil for them to live on, ate those of the Mustard, and the acidity contained in these roots killed them.

Nitrate of soda applied to a crop either kills the wireworm, or causes it to forsake the land. Amongst the numerous so-called remedies, we find spirits of tar mentioned, a diluted mixture of this substance and water not only driving away the wireworm, but causing most robust growth in the plants to which it was applied (French Beans) on sowing the seeds. Of the natural foes of the wireworm we may mention rooks, which are the greatest friends the farmer and the gardener have, and without which the former could scarcely hope to get any valuable returns from his land; wagtails, robins, blackbirds, thrushes, and probably sparrows. Pheasants and partridges are to be included among the farmers' and gardeners' friends, as is the lapwing or "pewit." Moles exercise an incredible amount of good in destroying the wireworm, and where these animals are exterminated, or greatly lessened in numbers, wireworm will be found in great abundance. Instances of this may be, in the experience of many of our readers, as most land contains the creatures. If my remarks should induce some readers of them to sow Woad or White Mustard in the garden, if wireworm prevent the healthy growth of Parsley, Carrots, Carnations, Sweet Williams, or other plants; or to save the moles and useful birds from destruction, and give their experience at some future time in these pages, they will not have been made in vain. *One of the Crowd.*

JAPANESE CHRYSANTHEMUMS AND SHOW-BOARDS.—Although the recent decision of the Chrysanthemum growers attending the meeting at the Royal Aquarium, and reported by you last week, was practically unanimous, we may take it for granted that the decision will not be largely acted upon this year. The change is of too great a kind to admit of general acceptance in some two or three weeks. Still farther, the matter will have to become the subject of a special rule or condition, which must be published in schedules before it can become binding. The fear expressed lest the decision to have such materially enlarged show-boards for Japanese flowers, will militate against the growth and exhibition of varieties of known beauty and quality, whilst it will give special impetus to the production of blooms that have chiefly size to recommend them, cannot be said to be baseless. The proposal certainly is a concession to the taste for big blooms, which features so largely dominate, whilst there seems to be no course open but to endure what cannot be helped. It would be a matter of the deepest regret were many fine old and truly beautiful forms banished from our tables; hence it does seem as if there is some reason for the retention of the present show-boards by establishing classes for Japanese varieties for flowers, which are under 6 inches in base diameter. That would still give encouragement to the growth of many sorts, the flowers of which whilst of ever such fine quality, would still look dwarfed when set up on the new large show-boards. Points that seemed to offer no difficulty at the Royal Aquarium will not be so easily got over elsewhere, especially in relation to the additional space required and the breaks in uniformity of boards, which will of necessity be introduced. Scores of the minor show blooms are not of the dimensions they are found at the Aquarium; and compulsion in the matter of the enlargement of the show-boards may lead to much opposition. The matter is very far from being a trivial one. Flowers of older and choicer varieties will look very small indeed in tubes 7 inches apart for front rows. There is really no reason why we should favour the wider production of big-flowered varieties of Chrysanthemums, any more than in such popular show flowers as Dahlias, Roses, &c. Given fair average size in these flowers, no one regards bigness as superior to density, form, and general quality. The Chrysanthemum men, never so refined in their tastes at any time as are the growers of old florists' flowers, seem disposed to place size before every consideration, so that one of the chief functions of Chrysanthemum exhibitors promises to be the encouragement of huge flowers chiefly, irrespective of general beauty or excellence. Such flowers as Elaine, Avalanche, Sunflower, M. Bernard, Criterion, &c., are large enough for anything, and perhaps, with the exception of Viviani Morel—not, by the way, an exceptionally large flower—there is hardly a new big-flowered variety that can equal them. What, then, is to be gained by the increase in the size of large blooms? Not quality, nor beauty, nor average usefulness, that is certain. It is very needful to regard the trade element in Chrysanthemums with some hesitation. We are getting

into this trade some of that element, which has been found so objectionable in connection with the cycling trade. We are cultivating a race of raisers and growers amongst gardeners, just as the cycle manufacturers have evolved a race of manufacturers' riders, and the fear is, that for other than really honourable motives, many new varieties which have flowers of great size, but inferior quality, may be pushed to the front. That seems a very probable outcome of the enlarged show-board movement. *D.*

THE CHRYSANTHEMUM SEASON.—Some idea of the untoward character of the Chrysanthemum season may be inferred from the fact, that the committee of the Royal Cornwall Chrysanthemum Show, which is held at Falmouth, find it necessary to postpone the exhibition, announced for November 2, for a fortnight. One would imagine that Falmouth would be a district that, for earliness, would compare with any part of the United Kingdom, and yet it has to thrust the fixture on a fortnight. The October show at the Royal Aquarium was shorn of a great deal of its proportions, owing to exhibitors who had entered not being able to get their flowers open. It would appear as if the height of the Chrysanthemum bloom will fall in the third week in November, instead of the second week, which is usual. *R. D.*

SOME INSECTS WHICH INFEST APPLE TREES.—The writer of the note on p. 530 betrays much ignorance of his subject. *Aporia crataegi* (the black-veined white butterfly) has been practically extinct in this country for many years, probably a quarter of a century. Certainly extinct so far as capability for damage is concerned, and it is now believed to be totally extinct. If your correspondent can give any locality where it still occurs, even in the most reduced number, he will gladden the hearts of collectors of British butterflies, and also hasten its utter extinction. *Vanessa polychloros* (the large tortoise-shell) has never, in my recollection, been a "destructive" insect in this country, at any rate, to Apple trees. It has become distinctly rare latterly round London, and, like many other British butterflies, is gradually becoming more and more localised and less common. As the perfect insect (like all the *Vanessæ*) hibernates and lays its eggs in the spring, it cannot be said to have lain *perdu* either in "webs" or "coccons" during the winter. *Porthesia chrysothorax* is in the egg state during the winter, and is the only one of the trio likely to do any damage whatever. As your correspondent is uncertain which of the three it was that robbed the trees of their foliage, let me suggest that it may not have been any one of them. *R. McLachlan.*

DAHLIAS.—Some corrections in the names of the Dahlias given on p. 526 are necessary. *R. T. Rollinson* should be *R. T. Rawlings*, *Mr. Gladstone* should be *Mrs. Gladstone*, *Gulielma* should be *Gulielma*, and *Northern Star* not *Northern India*; *Kyneth* is *Kyneth*, and *Robert Mayhew*, *Robert Maher*. Probably the varieties seen by your correspondent were so named, and as growers might be induced from the favourable notice given by your correspondent to order under these names, it is as well to correct them. *R. D.*

SOCIETIES.

ROYAL HORTICULTURAL.

NOVEMBER 1.—As is usual when November visits us, and we are submerged more or less in smoky fogs, and the weather is raw, the exhibits at the Drill Hall, James Street, Westminster, on Tuesday last showed a considerable falling off, as compared with the last one. There was, for the season, a good show of Orchids, a remarkable collection of *Nepenthes*, and they, with the help of a few well-flowered *Bouvardias*, and some *Chrysanthemums*—that were not so numerous as we should have expected—saved the Hall from having a dull appearance.

Floral Committee.

Present: *W. Marshall, Esq.*, in the chair; and *Messrs. G. Phippen, G. Paul, J. Fraser, H. Bennett-Pöe, C. Noble, T. Baines, W. Bain, C. Jeffries, H. Cannell, W. Furze, H. Turner, C. E. Pearson, T. W. Girdlestone, and B. Wynne.*

Prizes had been offered for a collection of *Chrysanthemum* blooms, distinct, without any dressing, and to be shown with foliage, as cut from the plant.

There were only two competitors, and neither of the collections could be described as anything other than ordinary. Those, however, that were placed 2nd—although, perhaps, the blooms were somewhat less in size—were staged in a pleasing and tasteful manner, and formed in this respect a striking contrast to those that were placed 1st. 1st, *S. J. Baker, Esq.*, Ottershaw Park, Chertsey (gr., *Thos. Osman*); 2nd, *The Duke of Northumberland*, Syon House, Brentford (gr., *Mr. Geo. Wythes*).

For twelve new *Chrysanthemums*, sent out since the beginning of 1890, *Mr. J. Douglas, Great Gearies, Ilford*, staged some good specimens of the following varieties:—*Edwin Beckett, Wm. Tricker, Mr. D. B. Crane, Viviani Morel, Alberic Lunden, Florence Davis, Madame M. Hoste, W. H. Lincoln (very fine), Gloire du Rocher, Viollet Rose, Bouquet des Dames, and Louis Behmer.*

An Award of Merit was given to *W. H. Atkinson*, a Japanese of dull red colour, with pale bronze reverse, large blooms, and medium broad petals, shown by *Mr. H. J. Jones, Ryecroft Nursery, Lewisham*. The same exhibitor had a Japanese called *Charles Bonstedt*, described as a November-flowering variety. Also a Japanese (October flowering) called *Vesuvius*, which looked like a good decorative variety.

Messrs. J. R. Pearson & Sons, Chilwell, obtained an Award of Merit for their Japanese *Emily Doone*, a large full flower, white with creamy centre, and bottom petals somewhat rose-coloured. It appeared to be of robust constitution. *Messrs. Pearson* also showed two large single varieties, *Mars*, crimson with yellow centre, and *Dawn*, a pretty pink variety; *Purple Queen*, of the Japanese section; *Mdlle. Nathalie Brun*, a good large *Anemone* flower, white with a yellow flush; and the new *Delaware*.

A very fine lot came from *Messrs. H. Cannell & Sons, Swanley*, and an Award of Merit was granted to *Golden Ball*, a good Japanese decorative variety, of exceeding rich golden-yellow, and full high centre. From *Swanley*, too, were twelve exceedingly large blooms of *Viviani Morel*, and twelve good blooms of *Col. W. B. Smith*, also some good blooms of *Mrs. C. H. Payne, E. Molyneux, Miss Watson, Jno. Dyer, Wm. Tricker, Amos Perry, Beauté de Toulousaine, Gloire du Rocher, Delaware, Chas. Gougnon, Ida Longhi, Mrs. H. W. Goulden, and Harry Balsley (Vote of Thanks).*

Mr. Horsfall (gr. to Mr. Morrall, Bellamour, Rugeley, Staffs.), had bloom of what appeared to be a Japanese incurved, of the hairy type, but which was not in good form. Also a very pretty *Croton* called *Beatrice Horsfall*, which was granted an Award of Merit.

A group of remarkably well-grown plants of *Bouvardias* came from *Mr. J. F. McLeod, gr. to J. Pierpoint Morgan, Esq., Dover House, Roehampton*, and included the doubles, *President Garfield* and *Alfred Neuner*, singles *Hogarth, Vreelandii, Elegans, Priory Beauty, &c. (Silver Banksian Medal).*

From the Royal Horticultural Society's garden, *Chiswick*, came some plants of *Begonias* in bloom, which had been in the flower-beds during the summer. The varieties were *Duchess of Connaught, Crimson Gem, Reading Snowflake, and Princess Beatrice.*

Two fine sprays of *Ixora Duffi* came from *Mr. R. Mackellar, Abney Hall Gardens, Cheadle (Vote of Thanks).*

A spathe of *Rhaphidophora lancifolia*, from *Lady Cane (gr., Mr. Poole).*

A fine pan of the beautiful *Begonia barbata*, from *Messrs. James Veitch & Sons, Chelsea*; also some plants of *Pandanus Baptistii*, a perfectly smooth *Pandanus*, with leaves about three-quarters of an inch wide, and very slightly variegated.

Messrs. B. S. Williams & Sons, Upper Holloway had plants of *Nerine Meadowbankii, N. corusca, and N. Moorei.*

Lord Rothschild, Tring Park, sent a new perpetual-flowering *Carnation*, which failed to find favour with the committee. The flower was of good form, and pretty cream colour, with slight magenta markings.

From *Mr. Anthony Waterer* came a group of autumn leaves, comprising *Andromeda arborea, Vaccinium corymbosum, V. pennsylvanicum, Quercus coccinea splendens, Andromeda mariana, and Acer palmatum.*

A First-class Certificate was awarded to *Hyca imperialis*, exhibited by the authorities of the Royal Botanic Garden, Glasnevin.

Orchid Committee.

Present: H. J. Veitch, Esq., in the chair; and Messrs. J. O'Brien (Sec.), Dr. M. T. Masters, F.R.S., T. B. Haywood, C. Pilcher, H. Ballantine, H. M. Pollett, J. Jaques, T. W. Bond, H. Williams, and W. H. White.

Messrs. B. S. Williams & Son, Victoria and Paradise Nurseries, Upper Holloway, N., exhibited an extensive group of Orchids, in which were the rare *Lælia Perrinii nivea*, a pure white flower, with a pink tip to the labellum (Award of Merit); *Cypripedium Iris* ×, a curious little hybrid; the handsome *C. Pitcherianum insigne* ×, *C. Pitcherianum* × *Williams* var.; *C. Wallaertianum* ×, some fine varieties of *C. insigne*, *C. Ashburtonia expansum* ×, *C. Arthurianum* ×, some handsome forms of autumn-flowering *Cattleya labiata*, of which one named *delicata* was almost wholly rose-pink, and a fine form; *C. Bowringiana*, *Dendrobium album* and other *Dendrobes*; *Pleiones*, *Oncidiums*, *Odontoglossums*, &c. (Silver Flora Medal).

Messrs. F. Sander & Co. also had a group, principally of new Orchids, some of them being of merit, and especially the new *Cymbidium Winnianum* × (*giganteum* ♀ × *eburneum* ♂), raised by Charles Winn, Esq., of Selly Hill, Birmingham. The specimen had five spikes of flowers, equal in size and form to those of *C. giganteum*, but of an ivory-white, the lip being beautifully spotted with crimson. The spikes bore from five to ten flowers (First-class Certificate). Another great beauty in Messrs. Sander's group was *Cattleya labiata Sanderæ*. The flowers were of a pearly bluish-white, the labellum with a blotch of violet-crimson within its broad white margin (Award of Merit). Others, handsome and striking, were *Brassia Sanderiana*, *Oncidium Saintlegerianum*, *Aogracum caudatum*, some noble forms of *Cypripedium insigne* and the true autumn-flowering *Cattleya labiata* (Silver Flora Medal).

Messrs. Jas. Veitch & Son, Royal Exotic Nursery, King's Road, Chelsea, showed three more fine hybrid Orchids in *Cattleya leucoglossa* × (*C. fausta* × ♂ (*exoniensis* × *Loddigesii*) × *Loddigesii* ♀). The plant is neat in habit, and the flower as large as an ordinary *C. labiata*. The wax-like flower is clear rose-pink, the ample front-lobe of the lip being white, the median portion clear yellow (First-class Certificate).

Another hybrid from the same nursery was *Cypripedium Arthurianum pulchellum* (*insigne* *Chautinii* ♂ × *Fairrieanum* ♀), which is a good *C. Arthurianum* with the addition of some crimson spotting in the upper sepal (Award of Merit), and a very curious one was *Dendrobium striatum* × (*Dalhousieanum* ♂ × *japonicum* ♀). The flowers were rose and white, and about the size of *D. nobile*, the shield-shaped lip being very curious.

Sir Trevor Lawrence, Bart., Barford Lodge, Dorking (grower, Mr. W. H. White), exhibited two cut spikes of a richly-coloured, well-grown *Spathoglottis Viellardii rubra* (First-class Certificate).

T. Statter, Esq., Stand Hall, Whitefield, Manchester (gr., Mr. R. Johnson), showed a good spike of *Lælia elegans* var. *excellens*, like a very richly-coloured *L. e. Turneri*, but with pure white tube to the labellum (Award of Merit).

Messrs. Hugh Low & Co., Clapton, staged a small group, in which were two fine *Vanda cœrulea*, a very good *Cypripedium Chamberlainianum*, *C. Leeaeum* ×, *C. Ashburtonia*, *Cattleya labiata*, a spike of *Lælia purpurata Schroderæ*, and a curious hybrid *Lælia* named *L. Claptonensis* × (*Dormani* ♂, *elegans* ♀). The flower more nearly approached *S. e. Schilleriana*, but when stronger it may develop more distinct features.

Messrs. Charlesworth, Shuttleworth & Co., of Heaton, Bradford, and Clapham, sent a fine plant of *Miltonia Bluntii Lubbersiana*, which had been previously Certificated; and H. Shaw, Esq., Stamford House, Ashton-under-Lyne, near Manchester (gr., Mr. J. Cliffe), exhibited a *Cypripedium* of the reputed parentage *C. lavigatum* × *Lawrenceanum*, but which bore no trace of *C. lavigatum*.

Fruit Committee.

Present: P. Crowley, Esq., in the chair; and Messrs. R. Hogg, H. Balderson, J. Smith, J. Willard, G. H. Sage, A. Dean, W. Warren, Geo. Bunyard, W. Wilks, H. Pearson, Harrison Weir, T. F. Rivers, G. Hammond, and J. Cheal.

Exhibits were few. Mr. W. Icton, nurseryman, Putney Park Lane, sent a basket of large-berried and well-coloured Alicante Grapes, and one of well-finished Gros Colmar, which the committee commended for their culture.

A collection of highly-coloured Apples came from Mr. T. H. Crasp, Canford Manor Gardens, and included Warner's King, Cox's Pomona, Mère de Ménage, Ribston Pippin, Fearn's Pippin, King of the Pippins, Blenheim Orange, Cox's Orange Pippin, Hollandbury, and Barcelona Pearmain (Bronze Bank-sian Medal).

A seedling Apple came from Mr. J. J. Kidd, Chase Nursery, Lynn. Mr. J. Watkins, Pomona Farm, near Hereford, sent dishes of Apples, Tom Putt, Pickering Seedling, and Devonshire Red (Vote of Thanks).

Mr. R. Milner, Penrice Castle Gardens, Swansea, received a Cultural Commendation for half-a-dozen Onions, Ailsa Craig; these were large and sound, and were sown in the open ground on Feb. 24, 1892.

Messrs. T. F. Rivers & Son were awarded a First-class Certificate for a new seedling Plum, River's Late Orange, of such excellent flavour that the specimens had all disappeared when we endeavoured to inspect them!

From the Society's garden at Chiswick were exhibited several varieties of Grapes, including Black Monukka, a variety that produces no seeds; also a collection of bunches of well-grown Turnips, and thirty-seven varieties of Savoy Cabbages.

LECTURE ON FRUIT TREES IN POTS.

In the afternoon an excellent lecture was given by the Rev. W. W. Wilks (Secretary to the Society). At the commencement the lecturer described the circumstances which had led him some six or seven years ago to turn his attention to orchard-house culture, in the hope of obtaining, by such means, a supply of Peaches, Nectarines, Plums, and Pears, which—through possessing no garden walls, and no means of obtaining any—he could not produce outside. After visiting Mr. Rivers' nursery at Sawbridgeworth, and Mr. Bunyard's at Maidstone—where the lecturer declared he had learned particulars to which the success of his efforts could be directly attributed—he built a house 48 feet long and 25 feet wide, and, although circumstances made it inevitable that the house should run from east to west, Mr. Wilks could not help thinking that a house so situated commanded the largest possible amount of light, and secured the greatest degree of shelter.

The question of heating was thoroughly threshed out, the pros and cons carefully weighed, with the result that a 4-inch flow and return was fixed, with the twofold object of protecting the blossom in spring, and providing winter protection for *Chrysanthemums*. Apricots were tried, but were a complete failure. Mr. Wilks then described the compost that was used for repotting the trees each year, the major proportion of which was fat yellow loam, with the usual addition of manures, and material for keeping the compost in an open friable state. Each tree is repotted every year. The compost was allowed to lie one month previous to use in a place sheltered from heavy rains. Mr. Wilks here described minutely how the process of repotting was effected, and laid a certain amount of importance upon getting as much of the old soil away as possible without severely crippling the roots. All woody roots should be cut off, and Mr. Wilks said that amateurs will generally err in not using the knife freely enough, whilst inexperienced gardeners would be sure to err in the opposite direction. The trees are potted in October, and are then plunged in the open, where they remain the whole of the winter. At the end of January the house is thoroughly cleaned out, the lecturer stating that a day's thorough cleaning at this period would save much trouble from thrips and green-fly during the season. Sometime during February—during absence of severe frost, and extreme wet—the trees are housed. No heat should be given until they are in flower, but plenty of ventilation is required, and a little attention to watering. From the first day the plants are brought in they should be syringed freely every day, and if the weather be bright twice during each day. About the beginning of March the buds would show signs of bursting, and before these expand the whole of the orchard-house trees are subjected to a thorough smoking, two nights in succession. As the flowers open, a little heat should be allowed at night, and in the day also, providing the weather is bad. Most of the Peaches and Nectarines, Mr. Wilks said, usually produced an overabundance of buds, in which case it was only necessary to give the tree a sharp knock with his hand during the middle of the day, in order to liberate sufficient pollen to secure a crop; but where a case occurred in which the fruit buds were not so plentiful, the camel-hair brush

was used, and pollen was preferred from trees of the small-flowered section. Plums required very little more attention in this respect, but the pollen was something heavier, and less easily distributed. The thinning of Peaches and Nectarines was commenced as soon as they were set, only leaving about one-third, which were again reduced as soon as the stoning was over. A similar method would do for the Peaches, but Pears required much less thinning. Just one or two are left in each cluster, and it is preferred to leave those at the base rather than at the apex. Mr. Wilks then described the pruning that be effected at this time. The Peaches and Nectarines had any needless shoots of last year removed, and the young shoots and leaders pinched back to about five leaves. On the Pears all side shoots are shortened to two or three leaves, unless required for extension. The leader of each branch is allowed to grow until June, when it was broken over, but not off, at the six or tenth leaf, according to the strength of the shoot. When the Pear tree has grown as large as it is intended to let it, the leader is allowed to grow all the summer, and is then cut out at the base.

As soon as the fruit is set, Mr. Wilks said he top-dressed all of them with a rich compost, using some turfy loam, dung, fine mortar rubble, and a good proportion of Clay's Fertiliser and Thomson's Vine and Plant Manure. This is kneaded, and placed round the side of the pot, to form a kind of basin round the plant for the admission of water. The lecturer said that he managed to keep a good supply of fruits from the middle of June to September. In this house he fruited twenty-eight Peaches and Nectarines, twenty-one Pears, and a dozen Plums. The trees are from 5 to 9 feet high. The average yield from the Peaches is three dozen from each tree, and Plums are as safe a crop. Pears were not so certain, and he used duplicates of these, only housing for fruit those that had a fair amount of fruit. Mr. Wilks had three times as many Plums as he could shelter in the house, and by bringing one-third in at different times he succeeded in maintaining a succession. Mr. Wilks concluded his paper with a list of varieties and notes upon them, which was reserved for insertion in the Society's *Journal*. Dr. Hogg (chairman) having invited discussion, Mr. T. F. Rivers said he would not allow his trees to stand the winter we had to pass through; that his experience was, that when orchard-house trees are kept in the house during the whole of the year they were more fruitful, and more healthy. Speaking of manure, Mr. Rivers said the cultivator must supply what he knew was required; and in fruits—especially stone-fruits—lime must be applied if good results are to be expected. Orchard-house trees in pots would go on fruiting for an indefinite time—to his own knowledge for upwards of forty years. High houses were not required. Mr. Geo. Bunyard wished to emphasise the statement that Pears should not be thinned before they have pipped. Mr. Cheal, of Crawley, also objected to leave his plants outside all winter; and Mr. H. Cannel reminded the audience once again of the necessity for keeping the foliage clean and healthy.

NATIONAL AURICULA AND CARNATION AND PICOTEE.

OCTOBER 25.—The annual meeting of the members of these societies took place at the Horticultural Club, Hotel Windsor, on the above date, Martin R. Smith, Esq., in the Chair. The report of the Committee of the National Auricula Society testified to the increasing interest taken in the cultivation of the *Primula* family, notably in the show and alpine varieties.

The report of the Committee of the Carnation and Picotee Society was lengthy, and set forth, that at the annual exhibition, held in July last, there were not only a full and extensive display of the florists types of the Carnation and Picotee, but the varieties of the border types were very numerous and particularly good. There was a good competition for the special prizes offered by Mr. M. R. Smith. The Self and Fancy varieties appear to rapidly grow in numbers, in variety and quality, and in the estimation of the public. Some groups of plants were also highly attractive, though unfortunately staged in a bad light. Allusion is made to the publication of the *Carnation Annual*, which had been sent gratis to all subscribers of ten shillings and upwards to the Society; and members desirous of having copies for distribution can obtain them at half the published price, on application to the Secretary. The

entire cost of publishing the manual had been borne by the President, who has also distributed seeds from fertilised flowers of Carnations. The Horticultural Club is thanked for permitting the meetings to be held in their room free of charge.

The financial statements made by the Treasurer showed that the income of the Auricula Society was £76 10s. 2d., including a balance of nearly £9 at the commencement of the year. Annual subscriptions realised £64 11s. On the other hand, prize money was paid amounting to £65 8s. 6d., and this, with other expenses, brought the payments up to £76 10s., leaving a small deficit. The balance-sheet of the Carnation Society was very satisfactory, in consequence of ninety-four new members having joined during the year, mainly through the exertions of M. R. Smith, Esq., the President. The balance at the beginning of the year was £21 15s. 2d., subscriptions amounted to £134 1s., and special prizes given by Mr. Smith £19 5s. On the other side, prizes had been paid amounting to £78 14s., the sum of £12 10s. had been added to the reserve fund, which now amounts to £40, various expenses come to about £20, and a balance is carried forward of £65 10s. 5d. The accounts were signed by the auditors, Messrs. W. Badcock and W. Wheelwright.

Sir J. D. T. Llewelyn, Bart., was re-elected President of the National Auricula Society; the Vice-Presidents and committee were re-elected, some additional names being added to both; the officers were also re-elected. An addition was made to the schedule of prizes by the introduction of a class for an exhibit of any species of Primulas, also Auriculas, Polyanthus, and Primroses, arranged for effect, in a space not exceeding 12 superficial feet; and it was announced that Mr. William Smith of Bishop's Stortford had offered a special prize of one guinea for the best green-edged Auricula, not in commerce, showing decided quality.

The President of the National Carnation and Picotee Society, Martin R. Smith, Esq., was re-elected, also the Vice-Presidents and committee, with additions, and the officers. The schedule of prizes was revised, and considerable extensions and additions made to it, involving an extra expenditure of some £30. It was resolved that the date of the Auricula Show should be April 25, and that of the National Carnation on July 25.

A vote of thanks to the chairman closed the proceedings.

NATIONAL CHRYSANTHEMUM.

OCTOBER 26.—A meeting of the Floral Committee of the above took place at the Royal Aquarium, Westminster, on the above date, Mr. R. Ballantine in the chair, a considerable number of blooms being staged. First-class Certificates of Merit were awarded to Mr. Wm. Seward, The Firs, Hanwell, for a richly-coloured Japanese, named William Seward, already described; and Japanese John Shrimpton, like the foregoing, a fine reflexed variety of bright chestnut-crimson, large, full, and of great breadth of petal. Lizzie Seward is a rich, bright amaranth-crimson, with silvery-pink on the reverse of the florets—distinct and promising, but not being in good condition, the committee wished to see it once more. A First-class Certificate was also awarded to Mr. C. Bick, gr. to Martin R. Smith, Esq., Hayes, Kent, for Japanese H. W. Atkinson, bright coral-red and salmon, in some of the flowers taking on a bright cerise—distinct in colour, and very fine. Some blooms of the same variety also came from Mr. E. Beckett, The Gardens, Aldenham House, Elstree, but rather brighter in colour, though not so finely developed. H. F. Tiarks, a reflexed Japanese of a showy tint of bright pale red, was commended. First-class Certificates were awarded to Mr. H. J. Jones, Ryecroft Nursery, Lewisham, for a plant of a decorative Chrysanthemum, Ryecroft Glory, of a bright yellow colour, dwarf, and very free; and for Japanese Col. W. B. Smith, a flower of the character of E. Molyneux, orange, with a golden reverse of floret, fine and distinct. Child of the Two Worlds, a white sport from Louis Böhmer, the Committee wished to see again; also Comte de Lurani, a pink and white Japanese; the petals were marked like the Comet Aster. Mr. Jones also had several other varieties. A First-class Certificate of Merit was awarded to Mr. W. H. Fowler, Claremont, Taunton, for Japanese Mrs. Herbert Fowler, pale amaranth, with silvery reverse, a fine variety, full, and distinct.

From Mr. William Wells, nurseryman, Earlswood, came Japanese John Dyer, a promising orange and yellow(?) variety, the committee wished to see

again; also the white sport from Vivian Morel, he has named Mrs. W. R. Wells. The committee hesitate to accept it as a fixed sport, as the first buds from Vivian Morel frequently come white, and Mr. N. Davis brought two plants of this variety to prove this, each with three blooms, and in both cases one was rose-coloured and the other two quite white. Mr. Wells also had several single or otherwise semi-double varieties, generally bright in colour.

From Mr. C. Gibson, The Gardens, Morden Park, Mitcham, came Japanese La Belle d'Algiers, a large reflexed Japanese variety, ivory-white, flushed with pink; and Day of Algiers, a large semi-double variety, in the way of E. Molyneux, having a large golden eye. A First-class Certificate of Merit was awarded to Messrs. Pitcher & Manda, Hextable, Swanley, for a large deep coloured golden-yellow Japanese, W. A. Wells, of a hairy or spiny character; and Japanese George Savage, white with primrose centre, the committee wished to see again. A First-class Certificate of Merit was unanimously awarded to Mr. R. Owen, nurseryman, Maidenhead, for his grand new incurved Baron Hirsch, shown in splendid condition, colour golden-yellow, suffused with amber, and slightly tinted with purple on the basal florets. Mr. Owen had a few other Japanese of a promising character.

Some inconvenience having been caused by exhibitors gathering about the table during the time the committee were sitting, it was unanimously resolved that in future no persons but those officially retained are allowed to be present at the sittings of the committee.

GOSPORT CHRYSANTHEMUM.

OCTOBER 27.—The Gosport and Alverstoke Chrysanthemum was the first society to hold its show this season. The Thorngate Hall was the place of exhibition. Cut blooms formed the more important part of the show, and were staged in large numbers, and of creditable quality.

For twenty-four varieties distinct, half to be Japanese, and the remainder incurved, Mr. G. Hawkins, gr. to E. Laphorne, Esq., Gosport, was an easy 1st, with compact blooms of medium size; and Mr. B. Sims, of 39, Shaftesbury Road, Gosport, was 2nd. For eighteen Japanese distinct varieties, Mr. Hawkins was again successful with fully-developed blooms of high colour. He was also the winner in the class for eighteen incurved varieties, with neat, if small blooms.

For twelve blooms of reflexed varieties, Mr. J. Hillier, gr. to S. T. Blake, Esq., Gosport, was an easy winner, with bright examples of the true type of reflexed flowers, and Mr. T. W. Hatch, Seafield, scored an easy win with twelve Japanese, his blooms being substantial specimens of popular varieties; Mr. J. Hillier made a creditable 2nd.

Pompons, considering the earliness of the show, were really meritorious. 1st, Mr. H. Lee, who staged them attractively in bunches of three; and 2nd, Mr. H. Dance, gr. to Mrs. Rowe, Gosport. Prizes were offered for the best examples of incurved and Japanese blooms, and both were taken by Mr. H. Lee with flowers found in his 2nd prize stand of eighteen varieties, the premier incurved award being taken by Gunner A. Holmes, R.A., Fort Grange.

Mr. G. Hawkins won the Certificate offered by the National Chrysanthemum Society for excellence of culture in the cut bloom classes. Mr. S. H. Watch staged a group of Chrysanthemums, meritorious in every respect.

Vegetables were numerous and excellent, and Mr. Hawkins won the highest award for nine kinds with very superior exhibits. Hardy fruit was also a feature, Mr. J. F. Legg being 1st for Apples, and Mr. Hawkins for Pears.

HAVANT.

OCTOBER 28.—The Town Hall was, as is customary, the site selected for this the ninth annual show of this Society. The flowers showed that a few days' more time would have developed them more fully than was the case; but, taken altogether, the display was fairly good.

In the cut bloom classes the interest chiefly centred, and many excellent stands were shown. For forty-eight, half to be incurved and the other half Japanese, eighteen varieties in all, Mr. Renford,

gr. to Sir F. W. FitzWygram, M.P., Leigh Park, Havant, was 1st, with an exceedingly bright stand of flowers Mr. Agate, the Chrysanthemum Nurseries, being a good 2nd.

For eighteen blooms of Japanese and incurved varieties, Mr. Steptoe, gr. to — Gale, Esq., Horn-dean, was 1st; Mr. Parrott, gr. to Mrs. Kuncaid Smith, won the 1st prize for twelve Japanese blooms; and Mr. Renford was 1st for twelve incurved flowers.

Mr. Agate was, as usual, to the fore with single-flowered and Pompons in bunches of three, taking 1st award in both classes with excellent specimens. Vivian Morel was premier bloom in the show.

Collections of miscellaneous plants and groups of Chrysanthemums rendered the hall very attractive, Mr. Taplin, Havant, winning in the former, and Mr. Agate in the latter.

Fruit and vegetables formed a notable feature in the display. Mr. Chignell, the Honorary Secretary, had, as usual, very satisfactory arrangements.

BRIXTON AND STREATHAM CHRYSANTHEMUM.

NOVEMBER 1.—Here was a fine all-round display of horticultural produce, gathered from the locality it represents. The plants (specimens) are not yet sufficiently advanced, wanting at least another week or ten days. The best (not Japanese) in the larger class came from Mr. Cherry, gr. to Mrs. Gabriel, Queen of England (very good), and Mrs. Dixon being two of the most noteworthy. For the corresponding class for Japanese, Mr. Cherry was also 1st. In the smaller class for three specimens, Mr. Clark, gr. to W. Griffiths, Esq., had some excellent examples, Margot being the finest (these were a very well-flowered lot).

The groups made a fine mass of colour, but the error so often made of keeping the back part too low and the front too high was in each case conspicuous. Mr. Poulton, gr. to C. T. Cayley, Esq., was a good 1st, many plants carrying blooms fit for boards, the colours were bright, the Japanese section being the strongest. Mr. Mursell, gr. to Mrs. Burton, came a near 2nd, lacking, however, in variety. Neither Pompons nor Standards were sufficiently in flower, although the plants were well grown.

In the cut-bloom classes, Mr. Howe, gr. to H. Tate, Esq., Park Hill, was invincible, showing many superb blooms. For twenty-four Japanese he was 1st, the whole set being very equal, with good variety in colour; the finest were Etoile de Lyon, W. E. Clark, Edwin Molyneux, Stanstead White, Mrs. F. A. Spaulding, and Mons. Holmes, none of the flowers being coarse. Mr. Mursell was here a good 2nd; Vivian Morel, Colonel W. B. Smith, and Majsatic were his best.

For twelve Japanese, Mr. Howe was also 1st; here he had Sunflower and Puritan in good form. For six, Mr. Gingell, gr. to Thomas Gabriel, Esq., was 1st.

For twenty-four incurved, Mr. Howe was 1st, having by far the best blooms, which wanted a few more days to perfect themselves; Lords Wolsey and Alcester, John Lambert, Empress of India, M. R. Bahuant, and Violet Tomlin were the finest, but all were remarkably even. The same exhibitor was 1st for twelve blooms.

One excellent class, which here meets with much favour, is that for twelve blooms shown upon long stems with foliage (as they should be). The best were twelve fine examples of Japanese, set up in Hyacinth glasses by Mr. Howe, making a most effective display. Several other good lots were staged in this class.

Another good class was that for broad-petalled Japanese, in which Mr. Howe again excelled, having Puritan, W. H. Lincoln, and Mrs. W. E. Clark as his best blooms. The Anemones were a pretty class, the 1st prize going to Mr. Pearce, gr. to Mrs. Fletcher Bennett.

The Miscellaneous plant classes were a fine feature in the show, the specimens not over large, but finely grown. Ferns are always shown well here. The 1st prize went to Mr. Wright, gr. to J. A. Whittard, who had a grand example of *Platycerium grande*, in fine health, *Gymnogramma schizophylla gloriosa*, and *Adiantum Farleyense*.

Orchids were exceptionally good also, the competition being remarkably keen. The most successful exhibitors were W. Ransom, gr. to J. T. Gabriel, Esq.; Mr. Jones, gr. to N. Sherwood, Esq.; and Mr. Howe.

Fruit was largely shown, Grapes, Pears, and Apples in season being the chief.

BRIGHTON AND SUSSEX NEW HORTICULTURAL.

NOVEMBER 1, 2.—The tenth annual exhibition of the Brighton and Hove Chrysanthemum Society was held in the Dome and Corn Exchange on the above dates. There was a very strong and close competition, and upwards of 600 entries, almost all of which were exhibited.

The chief prize-winners were residents in Sussex. That for a semi-circular group going to Mr. G. House, gr. to Mr. F. Mowatt, Patcham; Mr. Miles, Bristol Nursery, Kemp Town, being a close 2nd. For another group, Mr. Thorpe, West Hill Road, Brighton, was 1st; Mr. Fry, gr. to C. W. Catt, Esq., Brighton, being 2nd. The 1st prize for standards went to Mr. A. Scutt, gr. to Mrs. Jenkins, Burgess Hill. Mr. Scutt's name was very prominent throughout the show, so also were those of Mr. Meachen, Mr. G. F. Wickham, Mr. House, Mr. Fry, and Mr. Thorpe.

The chief prize of the day was for forty-eight large flowered, twenty-four incurved and twenty-four Japanese. The 1st prize was secured by Messrs. W. and G. Drover, Fareham, Hants; 2nd, Mr. Penfold, gr. to Sir F. W. FitzWygram, Bart., Havant; 3rd, Mr. C. Ritchings, gr. to Dr. Frankland, Reigate.

For twenty-four large-flowered Japanese, Mr. Glen was 1st; Mr. Wallis and Mr. Duncan following in the above order.

For a basket of Chrysanthemums, Messrs. Perkins & Son, Coventry, were 1st.

There was a good show of fruit, the quality being high throughout. In the open class for white Grapes, three bunches, Mr. Glen, Worth Park, Crawley, 1st; Mr. Phillips 2nd, and Mr. Kemp 3rd.

For black Grapes, three bunches, Mr. T. Fairs was 1st, Mr. Kemp 2nd, and Mr. Palley 3rd.

Vegetables were also good and numerous, but the prize-winners are perforce left out of this short report, owing to want of space.

Messrs. Balchin & Son, Messrs. Miles & Co., Messrs. J. Cheal & Sons, Messrs. Pitcher & Manda, and others exhibited, but not for competition.

The show was well attended, and may be considered one of the best held in the south of England.

EALING HORTICULTURAL.

NOVEMBER 2, 3.—The fifteenth annual autumn exhibition of Chrysanthemums, &c., was held in the Victoria Hall, Ealing, on the above date. For a group of Chrysanthemums arranged, Mr. C. Edwards, gr. to W. Owen, Esq., the Elms, was 1st, with a bold well-flowered collection. For a smaller group arranged in a space, 6 feet by 4 feet, Mr. C. Long, gr. to E. P. Oakshott, Esq., was 1st. Twelve bunches Pompons, 1st, Mr. C. Long; 2nd, Mr. W. Gates. Six bunches Pompons, 1st, Mr. C. Edwards; 2nd, Mr. C. Long. Six incurved, 1st, Mr. C. Edwards; 2nd, Mr. E. Jones, gr. to E. Hyde, Esq.

The premier incurved bloom was found in Mons. A. Bahuant, and the premier Japanese in Viviani Morel, both from Mr. C. Edwards, gr. to W. Owen, Esq. Six bunches Anemone-flowered.—1st, Mr. C. Edwards; 2nd, Mr. Long. There were many honorary exhibits, that helped greatly in the effect produced.

Grapes were well shown by Mr. F. Davis, gr. to E. Tautz, Esq.; and Mr. C. Edwards.

Hardy fruit and vegetables from local exhibitors made a creditable and extensive display.

ROYAL HORTICULTURAL OF ABERDEEN.

The acting directors of this society met in the office of the secretary (Mr. A. M. Byres) on the 21st ult.; Baillie Crombie was in the chair. The report, which was submitted to the annual meeting on Saturday, the 20th, states that the financial surplus on the year amounts to £435 18s. 9d., which, added to the balance brought from last year, makes £696 3s. 7d. at the credit of the society. Baillie Crombie was nominated for the chairmanship of the directors for the forthcoming year. The best thanks of the society were awarded to Lord Provost Stewart and Mr. A. M. Gordon, of Newton, chairman of the Aberdeen County Council, for their services in connection with the opening of the annual exhibition.

SCALE OF NUMBERS FOR SIZES OF APPLES.

It would be a great aid to uniformity in the descriptions of new varieties of Apples if we could adopt some scale of sizes, so that when we spoke of

a variety as being small, medium, or large, it would have a more definite meaning. At the present, the term medium size might convey to one person an entirely different meaning from what it would to another.

We notice in the last report of the Minnesota State Horticultural Society, an excellent suggestion by the Committee on Nomenclature. Speaking of the indefiniteness of the terms small, medium, large, and very large, they recommend a system of designating the size by a number from one to ten, starting at two inches in diameter, and adding one-quarter of an inch for each number. Numbers 1, 2 and 3 will then represent all under medium; 4, 5, 6 and 7, medium; and 8, 9 and 10, large. Any varieties, exceeding the diameter represented by these numbers would be designated as very large.

We have made a copy of this scale, and would suggest its adoption by our Association, for use in Canada.

Since writing the above we have corresponded

ratus, consisting of an india-rubber ball and air-chamber connected by a tube. A long brass-tube terminating in a nozzle serves to distribute the insecticide when pressure is made upon the india-rubber ball. The advantages claimed are that it does not choke, but will spray fluid containing sediments as readily as clean water. It will carry a distance of 12 feet. The spray is exceedingly fine, therefore economical, three minutes being occupied in distributing 1 quart of fluid at high pressure. Is easy to work; the spray reaches its height with a few pressures, and is then maintained with occasional attention. It sprays all ways equally well, including the upper and under surface of the foliage. We have tried it and found it to work well. In order to ensure perfect action, the fluid should not be allowed to get below a certain level, a matter which is easily arranged by filling up the can after it has been used, or by never allowing it to become quite empty. The inventor is Mr. Charles, chemist, Loughborough.

FIG. 87.—SCALE OF NUMBERS FOR SIZE OF APPLES.

with Mr. J. S. Harris, of La Crescent, Minn., who is the author of the table. He writes:—

"The square No. 1 should be exactly 2 inches, and each succeeding one $\frac{1}{4}$ inch larger, which will make the outside one, numbered 10, measure 4 $\frac{1}{4}$ inches, which is the size of the largest specimens of Apples grown in this State that have come under my notice. In describing by this method, the numbers are to stand for full average size of typical specimens of the variety. In numbering by this plan, I class all fruit measuring 2 inches or $\frac{1}{4}$ inch less, as size 1; from 2 to 2 $\frac{1}{4}$ inch, size 2, &c."

—Canadian Horticulturist.

NEW INVENTION.

ECONOMIC PEST SYRINGE.

MESSRS. MESSENGER & Co., of Loughborough, have submitted to us a useful form of syringe, or spray-apparatus, suitable for the application of insecticides to greenhouse plants. The liquid is contained in a tin can, provided with a handle for convenience of carriage, and to which is attached a spraying appa-

MARKETS.

COVENT GARDEN, November 3.

[We cannot accept any editorial responsibility for the sub-joined reports. They are furnished to us regularly every Thursday, by the kindness of several of the principal salesmen, who revise the list, and who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the supply in the market, and the demand; and they fluctuate, not only from day to day but often several times in one day. ED.]

MARKET still depressed. Grapes exceptionally heavy. Prices without alteration beyond Kent Cobbs, which are easier, owing to supplies coming in better. James Webber, Wholesale Apple Market.

POTATOS.

Market still continues firm for best samples, 75s. to 85s.; dark soil, 52s. 6d. to 57s. 6d. J. B. Thomas.

SEEDS.

LONDON: Nov. 2.—Messrs. John Shaw & Sons, Seed Merchants, of Great Maze Pond, Borough, London, S.E., report more business doing in American Red Clover Seed at advancing rates. Alsike White and Trefoil are without alteration. Rye-grasses, both Italian and perennial, keep firm. Of winter Vetches the supply is getting rapidly reduced. Choice new Königsberg Tares are now obtainable at tempting rates. There is no change in Rye. Canary seed keeps steady. In Hemp seed the late advance is well sustained. Mustard seed exhibits continued strength. In Rape seed the drift is upwards. For Peas and Haricots there is an improving trade. Linseed, Buckwheat, Ziti, and Millet, realise former terms.

CORN.

Averages.—Official statement of the average prices of British corn, imperial measure (bushel) for the week ending October 29, and for the corresponding period last year:—1892: Wheat, 28s. 8d.; Barley, 27s. 9d.; Oats, 17s. 11d. 1891: Wheat, 35s. 11d.; Barley, 30s. 7d.; Oats, 19s. 5d.

POTATOS.

SEITALFIELDS: Nov. 1.—Quotations:—Reading Wonder, 60s. to 70s.; Snowdrops, 60s. to 75s.; Sutton's Abundance, 50s. to 60s.; Bruce Magnums, 50s. to 65s.; Early Rose, 45s. to 50s.; Hebrons, 50s. to 65s.; Imperators, 50s. to 60s.; Magnums, 45s. to 65s. per ton.

BOROUGH: Nov. 1.—Quotations:—English Magnums, 55s. to 65s.; Hebrons, 60s. to 65s.; Snowdrops, 60s. to 70s. per ton.

FARRINGTON: Nov. 2.—Quotations:—Magnums, 60s. to 65s.; Snowdrops 65s. to 70s. per ton.

GENERAL AVERAGES: Nov. 2.—Magnums, 50s. to 70s.; Hebrons, 60s. to 70s.; Champions, 50s. to 65s.; Imperators, 50s. to 65s.; Early Rose, 45s. to 60s.; Snowdrops, 60s. to 75s. per ton.

FRUITS AND VEGETABLES.

SEITALFIELDS: Nov. 1.—Quotations:—Cauliflowers, 3s. to 7s.; Cabbages, 3s. to 5s.; Collards, 2s. 6d. to 4s. per tally; Seakale, 8d. to 9d. per punnet; Spinach, 1s. 6d. to 2s. per bushel; Brussels Sprouts, 1s. 6d. to 2s. 3d. per half-sieve; Greens, 1s. 3d. to 1s. 6d.; Carrots, 2s. to 2s. 6d.; Turnips, 2s. to 2s. 6d.; Parsley, 1s. 6d. to 3s. per dozen bunches; Beetroot, 2s. per bushel; Leeks, 1s. 9d. to 3s. 6d.; Endive, 8d. to 1s.; Cabbage Lettuce, 3d. to 6d.; Cucumbers, frame, 1s. to 1s. 9d. per dozen; Horseradish, 1s. to 1s. 2d.; Celery, 8d. to 1s. per bundle; Onions, English, 6s. to 6s. 6d. per cwt.; Spanish do., 5s. 6d. to 6s. 9d. per case; Belgian and Dutch do., 5s. 6d. to 6s. per bag of 110 lb.; Mustard and Cress, 1s. 6d. to 2s. per dozen baskets; Cos Lettuce, 8d. to 1s. per score; Carrots, 20s. to 50s. per ton; English Apples, 2s. 6d. to 6s. per bushel; American do., 9s. to 14s. 6d.

per barrel; Quinces, 1s. 9d. to 2s. 3d.; Pears, 3s. to 4s.; Prunes, 3s. to 4s.; Damsons, 3s. to 3s. 6d.; Bullaces, 2s. to 2s. 3d. per half-sieve; Tomatos, English, 4s. to 6s. per peck; do. foreign, 1s. 6d. to 2s. per box.

BOROUGH: Nov. 1.—Quotations:—Cabbages, 3s. to 4s.; Marrows, 3s. 6d. to 4s. per tally; Cauliflowers, 1s. to 1s. 9d. per dozen; Brussels Sprouts, 1s. 6d. to 2s. per half-sieve; Lettuces, 6d. to 1s. per score; Carrots, 2s. 6d.; Turnips, 1s. 6d.; Parsley, 1s. 6d. per dozen bunches; Onions, English 4s. 6d. to 6s. per cwt.; Horseradish, 2s. to 2s. 3d.; do., foreign, 1s. 6d. per bundle; Apples, English, 2s. 6d. to 10s. per bushel.

FARRINGTON: Nov. 2.—Quotations:—Turnips, 2s. 6d. per bag; Carrots, 2s. 6d. to 3s. do.; Parsnips, 3s. to 3s. 6d. do.; Onions, English, 5s. 6d. to 6s. per cwt.; Celery, 10s. to 11s. per round; Cauliflowers, 7s. to 7s. 6d. per tally; Onions, Spanish, 6s. 6d. to 7s. per case; Apples, Wellingtons, 4s. per bushel; King Pippins, 4s. do.; Pears, Marie Louise, 4s. 6d. do.; Damsons, 5s. do.; Lisbon Tomatos, 9s. per box.

HAY.

Averages.—The following are the averages of the prices at the principal metropolitan markets during the past week:—Clover, prime, 80s. to 115s.; do., inferior, 45s. to 75s.; Hay, best, 60s. to 112s.; do., inferior, 25s. to 50s.; and Straw, 20s. to 41s. per load.

THE WEATHER.

[By the term "accumulated temperature" is meant the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fabr. for the period named; and this combined result is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

The districts indicated by number in the first column are the following:—

- 0, Scotland, N. Principal Wheat-producing Districts—1, Scotland, E.; 2, England, N.E.; 3, England, E.; 4, Midland Counties; 5, England, S.
- Principal Grazing, &c., Districts—6, Scotland, W.; 7, England, N.W.; 8, England, S.W.; 9, Ireland, N.; 10, Ireland, S.; (* Channel Islands.)

THE PAST WEEK.

THE following summary record of the weather for the week ending October 29, is furnished from the Meteorological Office:—

"The weather over our Islands was very changeable. Heavy rain occurred from time to time in almost all districts; but, over the greater part of the Kingdom, several intervals of clear bright weather were experienced. During the earlier days of the week showers of sleet or snow were general in the N.W., N., and E.

"The temperature continued very low until the week drew towards its close, when it rose with great rapidity, and became high for the time of year. The average values for the period were in most districts 3° or 4° below the normal, and in 'Scotland, N.,' as much as 5°. The absolute minima were registered between the 24th and 26th, when the thermometer fell to 16° in 'Scotland, E.,' 17° in 'Scotland, W.,' 19° in 'Scotland, N.,' and 'Ireland, N.,' and to between 20° and 26° in all other districts, except

the 'Channel Islands,' where the lowest reading was 34°. The highest of the maxima, which were recorded either on the 28th or 29th, varied from 58° in 'Scotland, N. and W.,' to 62° in 'England, E.,' and the 'Channel Islands.'

"The rainfall just equalled the mean in 'England, N.W.,' but exceeded it elsewhere; in 'Scotland, E. and W.,' 'England, S.,' and the 'Channel Islands,' the excess was large.

"The bright sunshine exceeded the mean in nearly all districts; the percentage of possible duration ranging from 38 to 41 in Ireland, from 25 to 35 in England, and from 27 to 35 in Scotland. In the Channel Islands the percentage was only 24."

ENQUIRY.

"He that questioneth much shall learn much."—BACON.

PLANTER'S FRIEND.—Will some of our readers who are acquainted with Australian plants kindly inform C. PLATZ & SON, what species is meant by Planter's Friend.

NOTICES TO CORRESPONDENTS.

* PHOTOGRAPHS, DRAWINGS, OR SPECIMENS.—We shall be pleased to receive from our Correspondents notes relating to interesting Gardens, together with Specimens or Illustrations of interesting Plants. Although circumstances prevent us in all cases from reproducing them, we are nevertheless glad to receive them, and as far as possible to utilise them for the benefit of our readers.

BEAN: J. W. The Purple Bean, Fève Violette, of the French, probably. It resembles the July Bean, and is seldom grown owing to the coppery colour of the seeds.

BOOKS: Botany and Bowness, Henfrey's Elementary Course of Botany, 4th edition (John Van Voorst, Paternoster Row, London, E.C.)—WILLOW CULTURE: R. G. H. There is no large new work on the subject in the English language, but there is a manual on The Cultivation of the Willow or Osier, by W. Scaling. (Published by W. Kent & Co., Paternoster Row, London; and by W. Allen & Son, Caxton House Long Row, Nottingham.)

CAUTION: H. W. P. The plant is suffering from the Carnation fungus, Helminthosporium echinulatum, but no grubs were found. Burn all the affected plants.

CHRYSANTHEMUMS AND ASPHALTED PATHS: T. M. It is quite possible that the material of which the paths are made might injure the plants if the roots touched it. Can you not place something for the pots to stand upon, or remove them to a vegetable-quarter away from the walk. Perhaps some of our readers who may have experience of tarred or asphalted paths would furnish some facts concerning this matter.

CORRECTION: Gardening Appointment in Gardeners' Chronicle, October 29, for Woodbaskett read Woodbastwick.

DOUBLE-FLOWERED RICHARDIA ETHIOPICA: C. H. Not of rare occurrence.

DR. LVAL: J. B. The concluding paragraph was a mere memorandum, which was not intended for insertion. The moss was not named in honour of that botanist.

GRUB IN DOCK: R. W. M. Hepialus humuli—the ghost swift.

IRON-HURDLES: C. P. They are stock-in-trade, and therefore removable.

MAGNESIA: G. W. W.—It is used in the form of sulphate in admixture with salts of lime, potash; but we do not think it is, generally speaking, of much importance.

NAMES OF FRUIT: Anon. Apples: 1, Betty Geeson; 3, Crimson Queen; 4, Spürmer Pippin. Pears: 1, General Todleben; 2, Hayshe's Victoria; 3, Glout Morçean; 4, Small Uvedale's St. Germain; 5, Duchess d'Angoulême; 6, Styrian.—Hope. 1, Fine-apple Russet; 2, Calville Rouge Précoce; 3, Scarlet Nonpareil; 4, Striped Beving. Pear: Beurié d'Amans.—W. Potter. 1, Brabant Bellefleur; 2, Court Pendu Plat.—John Plat. 1, Vicar of Winkfield; 2, Doyenné Boussoch.—W. B. It Cellici; 2, Worcester Pearmain; 3, Braban, Bellefleur; 4, Kentish Goff; 5, Hoary Morning; 6, probably Bedfordshire Foundling. Others undeterminable.—W. D. 1, Roundway Magnum

Bonum; 2, Tom Putt; 3, Cox's Pomona; 4, Royal Somerset; 5, New Hawthornden; 7, Court Pendu Plat; 8, Hoary Morning; 10, Gloria Mundi, probably.—*H. H.* 1, Scorpion; 2, Keswick Codlin; 3, Duchess of Oldenburgh; 4, New Hawthornden; 5, Worcester Pearmain.—*B. J.* 1, Baumann's Red Winter Reinette; 2, Duke of Devonshire; 4, London Pippin; 6, Kerry Pippin?—*No.* 7. 1, Williams' Bon Chrétien; 3, Marie Louise; 4, 4, Easter Beurré; 5, Irish Pesch; 6, Rymer; 7, Lord Derby.—*W. R. F.* 1, Duchesse d'Angoulême; 2, Uvedale's St. Germain; 4, French Crab; 6, Minchall Crab.—*Geo. Wall.* 1, Brabant Bellefleur; 2, Adams' Pearmain; 3, Warner's King; 4, Cox's Pomona.—*J. W.* (from October 22). 3, Gansell's Bergamot; Duchesse d'Angoulême; 5, General Todleben; 6, Comte de Flandres.

NAMES OF PLANTS: *G. M.* 1, Adiantum decorum; 2, A. concinnum; 3, A. tenerum; 4, A. capillus-veneris; 5, A. Patotii.—*J. W. H.* Cattleya labiata var.—*S. S. D.* 1, Paulownia imperialis; 2, seems to be Basella tuberosa.—*Pat.* Colutea arborescens, Escallonia Philippiana.—*Wm. S.* 1, Crategus pyracantha; 2, Correa alba; 3, Reineckia carnea variegata; 4, Sonerila Hendersoni; 5, Dichorizandra undata.—*A Lover of Ferns.* 1, Adiantum capillus-veneris; 2, Cibotium Scheidei; 3, Adiantum cuneatum var.; 4, Nephrolepis exaltata; 5, Lastrea tenericaulis; 6, Pteris serrulata cristata; 7, Adiantum trap-ziforme Saucta Catherina.—*J. W.* Vanda tricolor variety. We know of no distinguishing name for it.—*H. J. R. Firenze.* Your plant is Gongora maculata, which varies much in colour.—*W. E.* 1, Alonzoa incisifolia; 2, Leycesteria formosa.—*R. W. P.* Odontoglossum grande.—*Western Mail.* 1, Dracana albicans; 2, Begonia Weltoniensis; 3, B. argyrostigma elegantissimum; 4, B. scandens; 5, 6, and 8, send in flower; 7, Begonia metallica; 9, Toxicophlæa spectabile.—*H. M. E.* Send again when in flower. Cannot be identified by the leaves only.

OCHID-LEAF DISFIGURED: *K. E.* The Celogyne-leaf shows evidence of the plant having been kept in too warm and close a house. Place the plant in a more airy situation, and afford it less water, unless when actively growing.

STRAWBERRIES AT CHRISTMAS: *T. T.* We should say that it is not possible, under ordinary circumstances, in this country.

SULPHATE OF COPPER AND SODA MIXTURE ON POTATOS: *W. Cousins.* The bine of the Red-skinned Flourball Potato showed by its firm tissues and general indications of freshness, that the one dressing on July 29 had been quite effectual in preventing the disease attacking a variety much subject to attack.

WEEDS IN LAWN: *Old Subscriber.* Purchase Watson's lawn sand, and apply it evenly over the turf after having spudded out the grosser weeds, and filled in the holes thus caused with loam. If you cannot get the lawn-sand, apply loam, leaf-mould and wood-ashes, all in a finely-sifted condition. Put them on the lawn at the end of the winter, bush-harrowing, and finally rolling the lawn. When it has disappeared afford another dressing.

WINTER-FLOWERING CARNATIONS: *Carnation.* In addition to those varieties you possess, select the following:—*Souvenir de la Malmaison*, pink, also the crimson and red varieties of it; *Queen Victoria*, crimson-flaked maroon; *Sir David Baird*, fine yellow; *Mrs. Reynolds Hole*, apricot, shaded terra cotta; *Flambeau*, yellow, flaked scarlet; *Winter Cheer*, scarlet, dwarf, compact, very free; *Germania*, fine yellow; *Lucifer*, rich scarlet, large and fine; *Miss Joliffe*, pink, free; and *Catherine Paul*, white.

WORM: *X* The creature is *Bipalium kewense* of Mosely. First observed at Kew, it has been found in many bothouses in England, the continent, S. Africa, and Australia. Its native country has not been ascertained.

THOMAS GREEN & SON, LTD.,

LEEDS and LONDON,

HORTICULTURAL ENGINEERS to HER MAJESTY THE QUEEN, call Special Attention to their Patent Wrought-Iron Municipal or Angular Chambered and Tubular

HOT-WATER BOILERS,

And others with SHELVES, and HOLLOW or ORDINARY CAST-IRON GRATE BARS.

SADDLE BOILERS, With WATERWAY RACKS and WELDED BOILERS, any of which are specially adapted for Halls, Ware-houses, Workshops, &c. They are the neatest, cheapest, most effective, and durable of any extant.

The MUNICIPAL and TUBULAR ones are remarkable for their great heating power, slow combustion, and the length of time the fire will burn without requiring attention.

These Patterns secured the FIRST and HIGHEST PRIZE—a SILVER MEDAL—at the Royal Horticultural Society's Exhibition, South Kensington, London, June 1, 1881.

MUNICIPAL PATTERN BOILER, THE BEST EXTANT.

— FRONT ELEVATION —

— LONGITUDINAL SECTION —

— SECTIONAL PLAN —

The longitudinal section gives a view of the fire-box, water space, flues, &c. The cross section gives a view of the fire-box, water space and V-shaped back. The front elevation shows it set in brickwork, which is necessary for this class of boiler.

TESTIMONIALS.

Re HEATING APPARATUS. Borough Engineer's Office, Municipal Buildings, Leeds, January 9, 1886.
MESSRS. THOS. GREEN AND SON, LTD., NORTH STREET, LEEDS.
 GENTLEMEN,—I have great pleasure in bearing testimony to the efficiency and satisfactory working of the Hot-water Heating Apparatus you erected in these public buildings.
 The buildings are four storeys high, and we have a total length of about 28,000 feet of piping in them, varying in size from 1½ in. to 6 in. diameter, with their connections, &c. The several offices and rooms can all be in operation at one time or separately, and the heat regulated by means of the valves to the temperature required, even in the coldest weather.
 Two of your Patent Municipal Pattern Boilers, No. 4, work the whole of this piping easily, although we have three of them fixed. They are very powerful and economical in the consumption of fuel, and I am pleased to be able to report of them and the apparatus so favourably.
 I am, Gentlemen, yours truly,
THOS. HEWSON, Borough Engineer.
 Morley House, Bagot, St. Saviour's, Jersey, November 10th, 1886.
 GENTLEMEN,—The large Municipal Boiler which you sent me last year is doing its work satisfactorily; it is heating 5000 feet of 4-inch pipe in one of my vineries, and I am quite sure that it has power to work a much greater length, while in cost of fuel it compares favourably with my other Boilers.
 I have now five of your Boilers in use, and I cannot speak too well of their heating powers, or their comparatively small consumption of fuel.
 MESSRS. THOS. GREEN AND SON, LTD., LEEDS.
 Yours faithfully, (Signed) **G. W. BASHFORD.**
 And HUNDREDS OF OTHER REFERENCES CAN BE GIVEN IF REQUIRED.

THE IMPROVED GARDEN GULLY
(VINCE'S PATENT).

This useful invention is a great improvement on the ordinary Garden Grating, and is especially suitable for hilly walks and drives. As they never get stopped by rubbish or sand they effectually prevent the washing away of the gravel in heavy storms, and they save half the labour in cleaning out the cesspools. The prices are:—

6-in., 1s. 6d.; 8-in., 2s.; 10-in., 3s.; 12-in., 6s. 6d.; 15-in., 8s.
(The larger sizes are very strong for carriage drives.)

FIXED. Full Particulars on application. Testimonials:—

From Mr. J. WILLARD, Head Gardener to the BARONESS BURDETT-COTTIS, Holly Lodge Gardens, Highgate, N., July 12, 1892.—“Dear Sirs, Having given your Improved Garden Gully a fair trial, I may say that it proves in use all that you claim for it, and in my opinion has, for the sides of walks and drives, many advantages over the ordinary grating. Perhaps the best proof I can give you of this is that, as opportunity offers, I intend to use them instead of gratings. Faithfully yours, J. WILLARD.”—To Messrs. VINCE & VINE.

From W. WALTON, Esq., Secretary to the LONDON CEMETERY COMPANY, The London Cemetery Company, 29, New Bridge Street, Blackfriars, E.C., July 25, 1892.—“To Messrs. VINCE & VINE, Highgate. I am very happy to testify that your Patent Garden Gully-Frames in lieu of the old-fashioned gratings answer admirably. They were by my authority fixed in a new pathway made in Highgate Cemetery, and in the recent thunder showers they were severely tested and were

most effectual in preventing the scouring of the gravel. At the inspection my Directors were much pleased with them, and gave instructions that they were to be used when required at Nunhead Cemetery.—I am, yours truly, W. WALTON, Secretary.”

From Messrs. CUTBUSH AND SON, Highgate and Barnet Nurseries.—“Highgate Nurseries, London, July 27, 1892.—Dear Sirs,—Referring to the Improved Garden Gully you fixed for us some months ago, we are glad to say it answers admirably. As you are aware, our Nurseries here are very hilly, and during the recent storms all the ordinary gullies were blocked, whereas yours was in good working order. We shall not hesitate to recommend the same to anyone requiring the gullies for sides of paths and carriage-drives, and we feel certain, when it is known, there will be a great demand.—We are, yours faithfully, WM. CUTBUSH AND SON.—Messrs. VINCE & VINE.”

If set across three Columns the lowest charge will be 30s.

Page, £8; Half Page, £4 10s.; Column, £3.

NOTICE TO ADVERTISERS.—In many instances Remittances in Payment of Repeat Advertisements are received without name, address, or anything beyond the postmark on envelope by which to identify the sender; this in all cases causes a very great deal of trouble, and frequently the sender cannot be identified at all. Advertisers are requested when Remitting to give their Names and Addresses, and also a Reference to the Advertisements which they wish repeated.

GARDENERS AND OTHERS WANTING SITUATIONS, 26 words, including name and address, 1s. 6d., and 6d. for every additional line (about nine words) or part of a line. These Advertisements must be prepaid. This scale does not apply to announcements of Vacant Situations, which are charged at the ordinary scale.

Births, Deaths, and Marriages, 5s. each insertion.

POSITION.—Advertisers are specially requested to note, that under no circumstances whatever can any particular position be guaranteed for advertisements occupying less space than an entire column.

POSTAL ORDERS.—To Advertisers, Subscribers, and Others.—It is very important in remitting by Postal Order that it should be filled in payable at No. 42, DRURY LANE, to A. G. MARTIN, as, unless the number of a Postal Order is known, and it has been made payable at a particular office, and to a particular person, it is impossible to prevent any person into whose hands it may fall from negotiating it.

N.B.—The best and safest means of Remitting is by POST-OFFICE MONEY ORDER.

Advertisements for the current week MUST reach the Office not later than Thursday noon.

All Advertisements should be addressed to the PUBLISHER.

Publishing Office and Office for Advertisements, 41, WELLINGTON ST., STRAND, W.C.

SUBSCRIPTIONS.

All Subscriptions payable in advance. The United Kingdom, 12 months, 15s.; 6 months, 7s. 6d.; 3 months, 3s. 9d. All Foreign Subscriptions, including Postage, 17s. 6d. for 12 months; Post-office Orders to be made payable at the Post-Office, 42, Drury Lane, W.C., to A. G. MARTIN.

Subscribers who experience any difficulty in obtaining their Copies regularly, are particularly requested to communicate with the Publisher (in cases of delay in the delivery by post, the cover should be forwarded with complaint).

ESTATE SALES.

The Best County Medium for Advertising Sales of Estates is

THE "WORCESTER HERALD,"

ESTABLISHED 1794.

The Leading County Paper. Extensive circulation among the upper and middle classes in Worcestershire and adjoining counties. Advertisers would do well to forward for reference and distribution plans and particulars of Estates, Catalogues of Machinery, Furniture, Books, and other Property advertised in the Columns of the "HERALD."

Sales of Stock and Agricultural Effects.

The "WORCESTER HERALD" is the most effective organ for giving publicity to announcements of this class. It is the leading Agricultural Paper in the County, and Circulates most extensively among Agriculturists in and around Worcestershire.

Farms to Let.

Land Agents, Estate Managers, and all having Farms to Let would do well to advertise in the "WORCESTER HERALD," the Leading County Paper. Specially adapted for bringing such notices before Tenant Farmers. Large circulation. Moderate charge.

Situations Vacant and Wanted.

For producing results the "WORCESTER HERALD" is recognised as a specially good medium. Cheap Rates.

PROPAGATOR and GROWER.—Soft-wooded Stuff, Stove Plants and Ferns, Cucumbers, Tomatos, and Vines. Age 26. Twelve years' experience.—R. S., 102, Queen's Road, West Walthamstow.

To Nurserymen

PROPAGATOR, or GROWER.—Age 23; well up in Hard and Soft-wooded Plants, Ferns, and Cut Flowers for Market. Eight years' experience in leading establishments. Excellent references.—N. W., 41, Wellington Street, Strand, W.C.

GROWER or SALESMAN.—Age 29. Advertiser seeks re-engagement as above; well recommended.—W. L., *Gardeners' Chronicle* Office, 41, Wellington Street, Strand, W.C.

JOURNEYMAN, Inside, under a Foreman.—Age 22; used to Table Decoration. Three years' good character.—F. FOWLER, The Gardens, West Stoke House, Chichester.

JOURNEYMAN (SECOND), in the Houses.—Age 18; four years' experience Inside and Out. Good character from last employer.—S. TROT, Yew Tree Cottage, Crawley, Sussex.

JOURNEYMAN (FIRST); age 22.—T. ROBINSON can highly recommend a young man (abstainer). Has been with him two years as above. Chrysanthemums, Plants, Fruits, &c.—Elfield House, Hokingbourne, Kent.

IMPROVER, in private Gardens; age 17; three years' experience.—Mr. MILSON, Claydon Gardens, Winslow, Bucks, would be pleased to recommend a sharp, active youth as above.

TO GARDENERS.—Situation wanted by a young Man (age 19), Inside, or Inside and Out. Good references.—W. J. BRITAIN, Britwell Road, Burnham, Bucks.

TO GARDENERS, &c.—Situation wanted in a Garden or Nursery; age 19; useful in Garden. Been in a Nursery six months; strong, could take third place in Garden.—T. B., Lowland Farm, N. Amersham, Bucks.

TO NURSERYMEN.—Situation wanted; age 22. Eight years' experience in Cyclamens, Primulas, Chrysanthemums, Tomatos, Tricolors, Geraniums, Pelargoniums, Potting, Watering, Tying, and General Soft-wooded Plants.—CHARLES EDMONDS, Hillingdon Nursery, Middlesex.

GLAZIER.—Well up in Greenhouse work; good Painter and Decorator; understands all House Repairs. Would like to have a Gentleman's Estate to keep in repair.—F. H. S., 1, Wellington Terrace, Church Road, Willesden, N.W.

DECORATOR, or SHOPMAN.—Young man (age 25); used to good West end Trade. Good character.—W. G. LAURI, 10, Knight-bridge Green, Knightsbridge, S.W.

SHOPMAN (ASSISTANT).—Four years' experience in Seeds, Plants, Bulbs, and Implements.—R., William Reil Seedsman, Aberdeen.

SHOPMAN, or ASSISTANT.—Age 25; ten years' experience. Good knowledge of Seeds, Bulbs, Plants, &c. Good references.—ALPHA, *Gardeners' Chronicle* Office, 41, Wellington Street, Strand, W.C.

SHOPMAN (ASSISTANT), Country preferred.—Age 19. Just completed three years' apprenticeship in Messrs. Wood and Ingram's Seed Department and Offices, and is highly recommended by them.—A. P., Messrs. Hurst & Son, 152, Houndsditch, London, E., or Messrs. Wood and Ingram, The Nurseries, Huntingdon.

ASSISTANT, in Seed Shop.—Age 21; five years' experience. Good reference.—W., 5, Drayton Road, Crofton.

SHOPMAN.—Age 32; fourteen years' experience in Nursery Seed Bulbs, &c. Good references.—A. J. S., *Gardeners' Chronicle* Office, 41, Wellington Street, London, W.C.

TO FLORISTS.—A young Lady seeks an engagement in a Florist and Nursery Business, either as SECOND HAND, or to take charge of small Florist and Seed Business. Good reference.—A., Wisteria Cottage, Egham.

TO FLORISTS.—A young Lady seeks engagement as ASSISTANT in Shop or Nursery. Well up in Bouquets, Wreaths, Sprays, &c.—A. B., 30, Lower Breck Road, Liverpool.

TO FLORISTS and FRUITERERS.—A young Lady desires re-engagement. Thoroughly trained in both branches. Can furnish highest references from previous engagements.—S. C. M., 17, Sterne Street, Shepherd's Bush.

HOLLOWAY'S PILLS.—Weary of Life.—Derangement of the liver is one of the most efficient causes of dangerous diseases, and the most prolific of those melancholy forebodings which are worse than death itself. A few doses of these noted Pills act magically in dispelling low spirits, and repelling the covert attacks made on the nerves by excessive heat, impure atmospheres, over-indulgence, or exhausting excitement. The most shattered constitution may derive benefit from Holloway's Pills, which will regulate disordered action, brace the nerves, increase the energy of the intellectual faculties, and revive the failing memory. By attentively studying the instructions for taking these Pills, and obediently putting them in practice, the most despondent will soon feel confident of a perfect recovery.

CHRYSANTHEMUMS.

We are indeed delighted, and it must be a surprise to all to see, year after year, and this season more than ever, how conspicuous are the varieties introduced by us, not only at Exhibitions, but in Private Collections, and at every Market they are the theme of conversation and admiration. Our "Colonel Smith" of last year adds another memento to our reputation.

Our proper method of preparing stools and cuttings for propagation has proved to be of the greatest advantage; the cuttings and plants supplied by us are of the greatest value in almost every instance, and when in competition they prove their superiority over the sickly draw-up stuff usually supplied.

Our house—now ready for a further supply, together with our 14,000 cuttings already struck in single pots—is such that professionals and amateur growers would be pleased to see. It would be wise to entirely renew all collections from our perfectly healthy stock, and doubly full of colouring power, so as to insure brilliancy next year.

JOURNAL OF HORTICULTURE, July 21, 1892, says of Chrysanthemums:—"If there are any stronger and healthier plants in existence than those at Swanley, or that will yield better cuttings, I should like to see them."

GARDENERS' CHRONICLE, November 5, 1892. "Mr. Cannell has some thousands of cuttings in small pots; propagating is going on rapidly in this well-appointed nursery."

Send for ours, the best and most correct ILLUSTRATED and DESCRIPTIVE CATALOGUE of all the best varieties in cultivation.

 - POPLAR, Weeping, Pyramids and Standards, 10 to 12 feet.
- KNAP HILL NURSERY, WOKING, SURREY.

THE Gardeners' Chronicle.

SATURDAY, NOVEMBER 12, 1892.

INGESTRE HALL.

THE old hall at Ingestre, built in 1331, and which was burnt down in 1882, was always allowed to be by capable judges one of the best surviving instances of Elizabethan domestic architecture. All the windows on the first and second floors were mullioned, and at each extremity of the south front, the principal façade, semicircular bay windows, continued up to the carved balustrade of the roof, stood out boldly, and in the centre was the usual projecting porch. There was an absence of gables, but this was atoned for by some fine Oriel windows. When the house was rebuilt after the fire, the architect tried to follow, as much as was possible, the original plan, and since a great quantity of the old bricks were used again, it will soon lose its present modern appearance.

Ingestre Manor was included in the earldom of Stafford in Doomsday Book; in the reign of Cœur de Lion it became by marriage the property of the Chetwynds, who were not originally a Staffordshire family. There was an unbroken succession till 1784, when the property again passed in the same way to Lord Talbot, who took the name of Chetwynd-Talbot. The most celebrated of the Chetwynds of Ingestre, was the antiquary, Walter Chetwynd, who was the Mæcenas of Plot, the author of the *Natural History of Staffordshire*, a very fantastic and antique tome. In 1860, after a long law suit, the House of Lords decided that the will of the seventeenth Earl of Shrewsbury in favour of the infant son of the Duke of Norfolk, was invalid so far as the entailed property was concerned. The successful claimant was Earl Talbot of Ingestre, who took the title of Earl Shrewsbury and Talbot, and thus became in addition the owner of Alton Towers, the most magnificent seat, not only in Staffordshire, but probably in England also.

The pretty church, built by "the antiquary," and surrounded by old tree-like Yews, is within a hundred yards of the south front. By ascending the tower, a bird's-eye view of the country can be obtained. To the south a turf-road stretches away to Cannock Chase, to the west are the thickly timbered woods of Chartley Park, where there is a herd of the wild cattle, while immediately below is the home park. This park presents a very pretty landscape, owing to glimpses of the Trent winding through it, and the gentle slope up to a ridge of trees. This line of big trees prevents the deer park, 400 acres in all, from being part of the view. On the east side a curving lawn has a background of shrubbery and coniferous trees, extending back a goodly distance. The walk thither passes the oft-written-about Irish Yews. There are four of them, forming a solid square, with a side of 24 feet

(LIMITED) **CHESTER.**

VICTOR POTATOS (SHARPE'S).

This favourite first early Potato, suitable for any Garden, indispensable for Forcing and Early Borders, and likely to take the first rank amongst first earlies for market use. Quality and yield all that could be desired. One well-known market grower has this year had a yield of 15 tons per acre on a large acreage. London and Manchester salesmen speak highly of their quality, and report that Victors will keep their bloom and have a fresh appearance after being in the market some days, when other early Potatoes have become discoloured and unsaleable.

The stock we offer is the true yellow-fleshed variety and not the white variety, which is often substituted.

Price per cwt. and ton. State requirements to

W. W. JOHNSON & SON,
Seed Growers and Merchants. Boston, Lincolnshire.

SPECIAL TRADE OFFER,

at reduced prices, as follows, all fine healthy trees:—
500,000 RHODODENDRONS, from 2 to 4 feet.
ASH, Common, 3 to 4 feet, 4 to 5 feet, 5 to 6 feet, 7 to 8 feet, 9 to 10 feet.
.. Mountain, 3 to 4 feet, 6 to 7 feet, 9 to 16 feet, 10 to 12 ft.
BEECH, Common, 3 to 4 feet, 4 to 5 feet, 7 to 8 feet, 10 to 12 ft.
BIRCH, 9 to 10 feet, and 10 to 12 feet, fine.
CHESTNUTS, Horse, 3 to 4 feet, 5 to 6 ft., 8 to 9 ft., 9 to 10 ft.
ELM, 3 to 4 feet, 6 to 8 feet, 9 to 10 feet, stout.
LIMES, red twigged, 6 to 7 feet, 8 to 9 feet, 9 to 10 feet.
PINES, Weymouth, from 2 to 6 feet, various sizes.
POPLARS, 3 to 4 feet, intermediate sizes up to 10 feet.
PRIVET, oval-leaf, 2 and 3 feet; evergreen, 3 to 4 feet.
THORN QUICK, many hundred thousand, from 4 to 6 years old, very strong; SYCAMORE, 6 to 10 feet; LILACS, PINES, Austrian, from 3 to 6 feet, fine trees; AUCUBAS, LAURELS; HOLLIES, various; BERBERIS AQUIFOLIA, 1½ to 2½ feet; BOX, YEW; ELDER, golden; IVIES, and general NURSERY STOCK.

For prices, &c., apply to ISAAC MATTHEWS and SON, The Nurseries, Milton, Stoke-on-Trent.

N.B.—Rhododendrons, early-flowering varieties, from 15 in. to 2½ feet, full of buds, at special low prices, for forcing. Over 500,000 to select from. Inspection invited.

and so high that a lofty arch has been cut through them. Individually or collectively these trees are, perhaps, unsurpassed, either for size or symmetry. Mr. Gilman, the head gardener, told me that when Dr. Moore first saw them, he retired to a moderate distance, and was lost for a while in wonderment, and with difficulty was induced to proceed. He afterwards wrote a description of them. On the north side is the formal flower garden, the only thing that intervenes between the house and the park.

The gayest and brightest part of the grounds is the terrace walk, which, starting some distance above the kitchen garden, runs the whole length of it. It is called the terrace walk because it is in three stages. At regular intervals, such as the end of each stage, there are arches of clipped Yew, with pillars of the same on either side. These Yew arches are said to be very old, but they show no signs of age. On both sides is an herbaceous border, with shrubs at the back. The brilliant glow of colour from this long extent of straight border was very striking, and there was no deterioration in brightness in any part, except about half way down, where a long conservatory was faced by a roseroy with a Yew hedge behind it; a lawn, at the angles of which were two Golden Yews, surrounded the roseroy. Under the hedge was a rockwork of Ferns and an unhealthy Araucaria, with only a few branches, which had been utilised as a support for some Honeysuckles, thus changing an unsightly object into a pretty one.

The conservatory can be best described as a Palm-house. Tall Dracenas and Latania, Pandanus, Scaforthia, Cycas, Alsophila, and Cyathea occupied the centre space. The back wall was covered by Begonias and Ferns fixed in the usual way. Mr. Gilman has ransacked the nurseries to procure all the free-flowering herbaceous flowers, but still has to fall back on the old favourites—Asters, Phloxes, Sunflowers, Delphiniums, and Tritomas. Very conspicuous among the shrubs at the back were the particular Japanese Maples, and some large specimens of Polygonum cuspidatum. The latter has jointed branches like a Bamboo, big cordate leaves, and large umbels of white flowers. Mr. Gilman's house, at the entrance to the kitchen-garden, is reached by turning to the left down a short walk lined with bedding-out flowers. As this border is continued into the kitchen-garden and there planted with Carnations, which were also in flower, his house is in the midst of the flowers he loves and cherishes.

Heavy crops of nearly all the culinary vegetables could be seen. Rousham Park and Veitch's Main Crop are the two Onions depended upon, and they never fail either in size or quantity, nor does the Lyon Leek. There was a large piece of Veitch's Autumn Giant Cauliflower, an invaluable kind. Apples were a fair crop, Small's Admirable being the most prolific, perhaps, although Worcester Pearmain came very close in this respect. A great number of Siberian Crabs are planted by the side of the walks; the tiny, ruddy fruits looked very enticing. Pear trees on a west wall were plentifully hung with fruit, and the sorts that hardly ever fail were bearing as standards. The vineries show evidences of good culture, and what is aimed at being an average number of bunches of good finish and flavour, which will not exhaust the Vines. This rule seemed to be broken, however, in a house of Lady Downes. White Tokay and Trebbiano still keep their place, the first rightly. In the Peach-houses only late varieties were in fruit. Two houses

are devoted to Melons, the varieties grown being Ingestre Hybrid and The Countess. Orchids are largely grown, and the range of houses containing them has on some occasions been worthy of a visit from the ubiquitous photographer. *Vagabond.*

NEW OR NOTEWORTHY PLANTS.

LYCOPodium MOOREANUM, Hort., Sander.*

This is a very distinct new species of Club-moss, which has been imported by Messrs. F. Sander & Co. from the north of Brazil, and sent out under the above name. For the specimen from which my description has been made, I am indebted to Mr. F. W. Moore, of Glasnevin, in compliment to whom it was named. Its nearest ally is *L. reflexum*, of Lamarck, var. *L. intermedium*, Spring.

Stem about a foot long, erect, laxly dichotomously forked from low down, moderately stout, including the leaves, one-third of an inch in diameter. Leaves crowded, lanceolate acuminate, one-eighth of an inch long, pale shining green, very concave at the base, pubescent on the face and edge, the upper not at all dwarfed. Sporangia placed in the axils of the leaves all down the stem. *J. G. Baker, Herbarium, Kew.*

ONCIDIUM SAINTLEGERIANUM, Rolfe, n. sp.†

This is a very distinct and striking species of *Oncidium*, introduced from South Brazil by M. St. Leger, and it has just flowered with Messrs. F. Sander & Co., of St. Albans, who exhibited it at a meeting of the Royal Horticultural Society on November 1. It belongs to Lindley's group *Tetrapetala micropetala*, and is allied to *O. bifolium*, Sims (*Botanical Magazine*, t. 1491), which, however, has a far smaller yellow crest, more yellow segments, shorter pseudobulbs and leaves, and other details. The crest of *O. Saintlegerianum* is very large, being a quarter of an inch across and nearly as high, and of a clear light maroon-purple shade, which makes a striking contrast with the clear bright yellow of the rest of the lip, and renders it more handsome than most of its allies. It cannot possibly be confused with any other species of this large and difficult genus. *R. A. Rolfe, Herbarium, Kew.*

ORCHID NOTES AND GLEANINGS.

FERNSIDE, BICKLEY.

IN Mr. H. M. Pollett's Orchid-houses, there is usually to be found a good show of flowers in some or other of the plants he so well cultivates. In one of the houses a fine lot of different varieties of *Cattleya labiata vera*, or autumn-flowering, was in flower, some of the specimens being far superior to that originally in cultivation under that name, and one of which is now in bloom at Fernside. It is evident that this variety of *Cattleya* is a great acquisition. The effect of the different varieties in Mr. Pollett's house, arranged with *Oncidium varicosum* Rogersii, *Dendrobium Phalaenopsis Schroderianum*,

* *Lycopodium Mooreanum*, Hort. Sander.—Caulis erecto modice crasso e basi laxè dichotomiter furcato, foliis confertis lanceolatis acuminatis firmis pallide viridibus facie et margine pubescentibus, supremis nullo modo reductis, sporangiis ad foliorum omnium axillas impositis.

† *Oncidium Saintlegerianum*, n. sp.—Pseudobulbus oblong, 2 inches long, somewhat narrowed above. Leaves linear-lanceolate, acute, 6 to 8 inches long, 5 to 10 lines broad. Scape 18 to 20 inches long, raceme (at present) nine-flowered. Bracts lanceolate, acute, 3 lines long. Sepals unguiculate, light brown, the dorsal one lanceolate-elliptical, concave, 5 lines long, the laterals united at base, then spreading, 6 lines long. Petals elliptical-ovate, subfalcate, undulate, otherwise like dorsal sepal. Lip paurate, three-lobed, 1 inch long; front lobe broadly subcordate-orbicular, apex bilobed, 1½ inches broad, undulate, clear bright yellow; side lobes minute, linear-oblong, obtuse, 1 line long, clear yellow; crest very large and prominent, clear light magenta-purple, 3 lines across by 2½ lines high, consisting of a central and two lateral rows of obtuse fleshy tubercles. Column wings broadly cuneate, obtuse, dull yellow, with some suffused reddish brown spots on basal half.

Lælia autumnalis alba, *L. anceps* varieties, *L. præstans*, &c., was very fine.

In the cool-house there is a fine show of *Odontoglossum grande*; a fine variety of *O. Uro-Skinnerii*, and some other species; and here was noted to be doing well a small plant of the richly-spotted *Odontoglossum crispum leopardinum*. *Cattleya Waracewiczii* (*gigas*) in its varieties is remarkably well-grown at Fernside in the shelter of a rockery planted with Ferns and foliage plants, and the gardener (Mr. Paterson) there says that they cannot be so well grown in any other house as in this situation. Of *Cypripedium* a large collection are grown, and a reason for their being in favour is that flowers are to be found on some of the species all the year round if a judicious selection of them be made.

CATASETUM LONGIFOLIUM.

These plants are very easily grown into good specimens, usually thriving best in small hanging-baskets, but this species (*Catasetum longifolium*) does best upon a block of wood, which enables its long leaves to hang down in a natural position, and the flower-spike being pendent, it is also seen to the best advantage when grown in this manner; but for the other species, if the baskets are well drained, they may be planted in good brown peat-fibre and chopped sphagnum moss in about equal proportions. They will do well in the growing season in the East Indian-house, as they require a great amount of heat, and also a fair share of water to their roots, and moisture in the atmosphere. The species are all deciduous, and after the bulbs are nicely finished off, the leaves will fall away, when water should be entirely withheld, and the temperature reduced, the cool end of the *Cattleya*-house being amply hot enough, and here the bulbs are not likely to suffer from drought. After re-potting in spring, the young growths first begin to start, and this is the only time one requires to be careful in watering, in order to avoid the water remaining in the young and tender shoots, which is apt to rot them; and as the spike mostly appears with the young growth, or when that is about half-made, the flowers get affected in a like manner. *Orchid Album*, vol. x., pt. 114.

CYPRIPEDIUM PITCHERIANUM X.

A fine hybrid, raised in the Victoria Nursery by Mr. Williams, between *C. Harrisianum* var. *superbum* and *C. Spicerianum*. *Orchid Album*, t. 453.

DENDROBIUM CILIATUM.

A Burmese species, with relatively small white flowers, and a triangular, yellow, ciliated front lobe to the lip. *Orchid Album*, t. 454.

CYPRIPEDIUM ORPHANUM X.

A hybrid, supposed to be between *Druryi* and *C. barbatum*, raised by Mr. Seden in the Veitchian Nurseries. *Orchid Album*, t. 455.

CATASETUM LONGIFOLIUM.

A handsome species, with flowers of a greenish-yellow, tipped with crimson. *Orchid Album*, t. 456.

LIST OF GARDEN ORCHIDS.

(Continued from vol. ix., p. 670.)

TRIBE VANDEÆ.—Anther operculate, cells mostly confluent. Pollen masses waxy, with a distinct stipes and gland, together forming a compound organ called the pollinarium.—A very large tribe, widely diffused in tropical and subtropical regions.

SUB-TRIBE EDLOPHIÆ.—Terrestrial or more rarely epiphytic herbs, with underground tubers or aerial pseudobulbs, plicate-veined leaves, and simple or branched racemes of flowers. Lip variously gibbous, saccate, or spurred, attached at the base of the footless column.—Three genera, and over 180 species, common in the tropics and subtropics of Africa and Asia, rare in America and Australia.

89. *EULOPHIA*, R. Br., in *Bot. Reg.*, viii. (1822), t. 686; Benth. et Hook. f., *Gen. Plant.*, iii., p. 535. *Eulophus*, R. Br., in *Bot. Reg.*, vii. (1821), sub t. 573 (not of Nutt.).—Sepals and

petals similar, or the latter rarely broader. Lip variously gibbous, saccate, or spurred. Species probably over 100, with the distribution of the subtribe. The genus is scarcely distinct from *Lissocilius*, into which it seems to pass almost imperceptibly. The majority of the species, however, are very easily distinguished. *Cyrtopera* only differs in possessing a distinct foot to the column.

(1.) *E. DELLA*, N. E. Br., in *Gard. Chron.*, 1889, pt. II., p. 210.—E. Trop. Africa. Introduced by Mr. James O'Brien from the Zambesi district, and flowered in the collection of W. E. Gumbleton, Esq., of Cork, in 1889. According to dried specimens, collected by Dr. Meller, it is a native of the Manganja Hills.

(2.) *E. CAFFRA*, Rehb. f., in *Flora*, xlviii. (1865), p. 186.—Zululand. Flowered in the collection of R. Warner, Esq., of Chelmsford, about the year 1865.

(3.) *E. CALLICHROMA*, Rehb. f., *Otia Bot. Hamb.*, p. 116.; N. E. Br., in *Gard. Chron.*, 1889, pt. II., p. 298.—E. Trop. Africa. Introduced from the Zambesi district by Mr. James O'Brien, with whom it flowered in August, 1889. It was originally collected on the Manganja Hills by Dr. Meller.

E. carinata, Lindl. = *E. VIRENS*.

(4.) *E. ENSATA*, Lindl., *Bot. Reg.*, xiv. (1828), t. 1147.—S. E. Africa. Introduced from South Africa, and flowered with Mr. Tate, of the Sloane Street Nursery, in July, 1827. Lindley remarks that he believes it was sent by G. Don from Sierra Leone to the Horticultural Society in 1822, but this evidently refers to some other species.

(5.) *E. EUGLOSSA*, Rehb. f., ex Batem., in *Bot. Mag.*, xcii. (1866), t. 5561. *Galeandra euglossa*, Rehb. f., in *Bot. Zeit.*, x. (1852), p. 935.—Sierra Leone. Introduced and cultivated by Messrs. Loddiges, of Hackney, though the precise date is not recorded. It flowered on the continent in 1852, and at Kew, from plants sent by Gustav Mann from the Old Calabar River, in 1866.

(6.) *E. GRACILIS*, Lindl., *Bot. Reg.*, ix. (1823), t. 742; Lodd., *Bot. Cab.*, xii., t. 1178. *Galeandra gracilis*, Lindl., *Gen. and Sp. Orch.*, p. 187; *id.*, in *Journ. Linn. Soc.*, vi., p. 133. *Galeandra extinctoria*, Lindl., *Gen. and Sp. Orch.*, p. 187.—Sierra Leone. Sent by G. Don, a collector in the service of the Horticultural Society of London, early in 1822, and flowered in their garden at Chiswick "almost throughout the summer" of that year.

(7.) *E. GUINEENSIS*, Lindl., *Bot. Reg.*, viii. (1822), t. 686; Lodd., *Bot. Cab.*, ix., t. 818; *Bot. Mag.*, t. 2467; Warn. and Will. *Orch. Album*, ii., t. 89.—Sierra Leone. Sent by G. Don to the Horticultural Society of London in 1822, and flowered for the first time in Europe shortly afterwards.

E. Helleborina, Hook. = *HADENARIA HELLEBORINA*.

(8.) *E. LATIFOLIA*, Rolfe, in *Bolet. Soc. Brot.*, (ined.).—W. Trop. Africa. Introduced from the small island of St. Thomas, and flowered in October, 1889, in the Jardin Botanique, Coimbra, whence it was sent to Kew by Professor Henriques. The leaves are small, elliptical-ovate, light shining green, with irregular transverse darker veins, and the flowers white, with purple lines on the lip.

(8.) *E. LEDIENII*, Stein, in *Verh. Schles. Ges. Nat. Kult.*, 1886, ex Stein, in *Gartenflora*, xxxvii., p. 609; N. E. Br., in *Kew Bull.*, 1889, p. 90. *E. maculata*, Stein, in *Gartenflora*, xxxvii. (1888), p. 609, t. 1285 (not of Rehb. f.).—W. Trop. Africa. Introduced from the Congo in 1885 by Von Ledien, and flowered in the Breslau Botanic Garden in the spring of 1887. Very closely allied to *E. maculata*, Rehb. f., but differing in its whitish-grey leaves, on which the spots are arranged in irregular transverse bands; also in certain floral details. The species appears to have been in cultivation in 1861, for there is a note from Van Houtte in Lindley's *Herbarium*, relating to a species like *E. maculata*, from the island of St. Thomas, W. Africa, whence I have seen *E. Ledienii*, received by Professor Henriques of Coimbra.

(9.) *E. LUNIDA*, Lindl., *Gen. & Sp. Orch.* (1833), p. 182; *id.* *Pot. Reg.*, xxi., t. 1821; *Limodorum luridum*, Avel., in Pers., *Synops.*, ii. (1807), p. 521.—Sierra Leone. Introduced by G. Don in 1822, and flowered in cultivation soon afterwards. It is said to be extremely common on the trunks of trees in some parts of the colony. Lindley's figure was made from a plant which flowered with Messrs. Loddiges of Hackney in January, 1836.

E. Mackaiana, Lindl. = *ZYGOPETALUM INTER-MEDIUM*.

(10.) *E. MACKENII*, Rolfe, n. sp.—In habit and general character closely resembling *E. maculata*, Rehb. f., but the leaves are shorter, relatively broader, and less acute, and the dark green spots are arranged somewhat transversely in irregular bands on a lighter grey ground. The segments are also shorter, the lobes of the lip broader, the front lobe sessile, instead of being separated from the side-lobes by a broad claw, and the spur shorter and stouter.—Natal. Collected by Mr. McKen, near Verulam, and again at Cudmore; also by Mr. Sanderson. Flowered at Kew in July, 1891, from specimens sent from Natal by Mr. Staden in the preceding year. It is named after Mr. McKen.

(11.) *E. MACROSTACHYA*, Lindl., *Gen. & Sp. Orch.* (1833), p. 183; *Bot. Reg.*, xxiii., t. 1972; *Bot. Mag.*, t. 6246.—Ceylon and S. India. Sent to the Horticultural Society of London by Mr. Watson, Superintendent of the Botanic Garden at Peradeniya, some years prior to 1837.

(12.) *E. MACULATA*, Rehb. f., in Walp. *Ann.*, vi., p. 647. *Angracum maculatum*, Lindl., *Coll. Bot.* (1821), t. 15; *id.*, *Bot. Reg.*, viii., t. 618. *Eceoclades maculata*, Lindl., *Gen. & Sp. Orch.*, p. 237 (excl. syn. A. Rich.). *Acrobium maculatum*, Spreng., *Syst. Veg.*, iii., p. 718. *Godorum pictum*, Link et Otto, *Jc. Pl. Sel. Berol.*, p. 35, t. 14.—Brazil and Paraguay. Introduced by Messrs. Loddiges, of Hackney, who flowered it in December, 1820. This species has three very near allies, namely, *E. Ledienii*, Stein, from West Africa; *E. Mackenii*, Rolfe, from Natal; and *E. monophylla*, S. Moore, from Mauritius. Thus the distribution of the group is very interesting. All have coriaceous, more or less variegated leaves.

E. maculata, Stein. = *E. LEDIENII*.

(13.) *E. MEGISTOPHYLLA*, Rehb. f., in *Flora*, lxviii. (1885), p. 379; *id.*, *Gard. Chron.* (1885), pt. ii., p. 787; Carr., in *Revue Hort.* (1887), p. 87, fig. 21.—Comoro Islands. Introduced by M. Leon Humbert in 1885, and flowered in the Jardin des Plantes, Paris, in 1887, under the charge of M. Lowry.

(14.) *E. MONOPHYLLA*, S. Moore, in Baker *Fl. Maurit. & Seych.*, p. 360. *Angracum monophyllum*, A. Rich., *Orch. Maurit.*, p. 66, t. 9; Bojer, *Hort. Maurit.*, p. 315.—Mauritius. Flowered in the Kew Collection in July, 1891, from plants sent home by C. W. Bewsher, Esq., of the Oriental Bank, Mauritius, in the preceding year. Very near *E. maculata*, Rehb. f., but the leaves are of a peculiar grey, suffused with a coppery tint, and with few olive-green spots arranged somewhat in irregular transverse bands.

(15.) *E. PULCHRA*, Lindl., *Gen. & Sp. Orch.* (1833), p. 182; Rehb. f., in *Gard. Chron.*, 1882, pt. i., p. 732; *id.*, 1884, pt. ii., p. 102 (var. *divergens*, Rehb. f.); *Limodorum pulchrum*, Thouars, *Orch. Iles Afr.*, tt. 43, 44; *Eulophia striata*, Rolfe, in *Journ. Linn. Soc.*, xxix., p. 53.—Bourbon, Madagascar, and Comoro Islands. Introduced from the latter by Hildebrandt, and flowered with Herr Kittel, of Eckersdorf, near Berlin, in 1882. The variety *divergens* flowered with W. Vanner, Esq., of Chislehurst, in 1884. When I described *E. striata*, I quite overlooked *E. pulchra*, Lindl., there being then no specimen either in Lindley's or the General Herbarium at Kew.

(16.) *E. SAUNDERSIANA*, Rehb. f., in *Bot. Zeit.*, xxiv. (1866), p. 378; *id.*, *Xen. Orch.*, ii., p. 174, t. 173.—W. Trop. Africa. Introduced by Gustav Mann, and flowered in the collection of Wilson Saunders, Esq., of Hillfield House, Reigate, in 1866.

(17.) *E. SCRIPTA*, Lindl., *Gen. & Sp. Orch.* (1833), p. 182; Rehb. f., in *Gard. Chron.*, 1872, p. 1003; *id.*, 1878, pt. 2, p. 332. *Limodorum scriptum*, Thouars, *Orch. Iles Afr.* (1822), tt. 46, 47.—Bourbon and Madagascar. First flowered in the collection of M. Pescatore, of St. Cloud, near Paris (date unrecorded); then with Wilson Saunders, Esq., of Reigate, in 1872.

E. squalida, Lindl. = *CYRTOPERA SQUALIDA*.

E. streptopetala, Lindl. = *LISSOCILIUS STREPTOPETALUS*.

E. striata, Rolfe = *E. PULCHRA*.

(18.) *E. VIRENS*, Lindl., *Gen. & Sp. Orch.* (1833), p. 182; *Bot. Mag.*, t. 5579. *Limodorum virens*, Roxb., *Pl. Corom.*, i. (1795), p. 32, t. 38. *Eulophus virens*, R. Br. in *Bot. Reg.*, vii. (1821), sub t. 373. *Eulophia carinata*, Lindl., *Gen. & Sp. Orch.*, p. 183.—Ceylon and South India. Sent by Dr. Thwaites, from the former locality, to Kew, where it flowered in January, 1866. R. A. Rolfe.

(To be continued.)

AGRICULTURAL GRASSES.

EVERY thoughtful farmer and grazier realises the importance of the production on his land of a good supply of grass for pasturage and hay. He who can produce the greatest yield on a given number of acres will be the most successful man.

In the United States they have many climates, many geological formations, many degrees of aridity and moisture; it must be apparent, therefore, that one species of grass cannot be equally well adapted for growing in all parts of this extensive territory, yet it may be said that hardly a dozen species of grasses have been successfully introduced into their agriculture. True it is that this number answers with a tolerable degree of satisfaction the wants of an extensive portion of the United States, chiefly the northern and cooler regions. But it is well known that in other localities the same kinds of grasses do not succeed equally well, and one of the most important questions for those regions is to obtain such kinds as shall be thoroughly adapted to the peculiarities of climate and soil. The grasses of cultivation were once wild grasses, and are still such in their native homes. The question naturally has arisen whether a selection from some of the wild or native species could not be made which will be adapted to cultivation in those portions of the country which are not provided with suitable kinds.

Many observations and some experiments in this direction have already been made, and the thanks of the farmers of our own country are largely due to Messrs. Sutton of Reading, and those of the United States are due to Dr. Geo. Vasey, the botanist of the Washington Department of Agriculture, and to Mr. Clifford Richardson, the assistant chemist of the same department, for their special report on the grasses of that country, which are either native or naturalised, and which have more or less agricultural value.

For a long time the botanists of the United States have felt the want of a general work on the grasses of that country; and Dr. G. Vasey has now issued an exceedingly useful monograph of the grasses of the United States and British America.

The present issue now before us is but the first portion of the work, the remaining part is expected to follow within the next few months. *J. J. Willis, Harpenden.*

FLORISTS' FLOWERS.

THE AURICULA.

WE have now passed into winter, and for two months at least Auriculas may be said to be quite dormant; and yet it is not prudent to neglect them. The large outer leaves now rapidly decay, and this is accelerated by frosts; and when the plants are

frozen, it is best not to disturb them at all. The plants become very dry at the roots if afforded no water, but I am careful to afford them enough to prevent shrivelling of any part. When the outer leaves are quite decayed, these should be cleared away; but I fancy it is not wise to pull off half-decayed leaves, the stems getting thereby injured. The lights are tilted whenever the weather is favourable; on fine days drawn off altogether, and in cold foggy weather and during severe frosts they remain closed, but no mats are used before Christmas. The plants seem all the better for a sharp touch of frost that freezes the soil in the pots, and when this occurs for some weeks, the *Auricula aphix* (*Trama Auriculæ*) suffers considerably, and does not recover sufficiently to do harm till after flowering. Drip is bad for Auriculas, if it fall in the centre of a plant, and, perhaps, may cause rot. See therefore that the glass is sound. The tiny seedlings which have been appearing above ground ever since July should not be checked by allowing frost to reach them, but they should be kept steadily growing, the flower pots or pans containing the plants being placed near the greenhouse or pit roof, where they may remain until January, when they should be pricked out as soon as the true leaves are formed. Plants will continue to vegetate during February and the following months. The alpine Auriculas out of doors now look well, and tree leaves that gather around the plants should be cleared away, as they harbour slugs. The decayed leaves of the Auriculas, which appear later, must also be removed from the plants.

CARNATIONS AND PICOTEES.

The plants in small pots are now well established, and in these they will pass through the winter. Some growers arrange their plants on stages in the wintering frames, in order that the water with which they are supplied may rapidly drain away, and when thus treated, the plants remain healthy, and suffer but little, even from the severest frost. Others plunge the pots up to the rims in some Cocoa-fibre refuse, for instance; still I do not think the plants do so well when the pots are plunged. Mine stand on damp fibre or spent tan, but they are not plunged; and they do very well so, and one severe winter, when many Carnations in frames were lost, I did not lose a single plant from frost. The plants are never allowed to get quite dry, and when water is required, it is afforded in the morning of a fine day, when air can be plentifully given. The plants should not be crowded together closely, or the leaves will decay. I never expose the plants to heavy rain, although a shower, if the weather is not very cold at the time, would not be likely to do much harm. Some of my Carnation frames face the south, and some the north, and they do well in both. Cleanliness, plenty of ventilation as soon as the plants are established, and the avoidance of drip, are the essentials to success, either for exhibitors or others.

Out-of-doors, the plants are looking very well, especially the seedlings. The appearance of the foliage from the different crosses is quite a study, and affords much interest to the cultivator. The named varieties and selected seedlings have not been long planted, but they are already well-established, as only those were planted that were well-rooted. This year they were planted out three weeks earlier than in 1891. The plants of the Malmaison type are usually layered earlier than others, and the plants potted up one month earlier, but by far the best plants, both as regards flowering and appearance, are those propagated from cuttings in the spring and early summer. The plants are wintered in a house which can be heated, in preference to keeping them in cold frames, for the reason that the plants are required to be in flower before the ordinary stock of Carnations. I had a fine display last June from plants like these which were not really forced, they having had no heat except that afforded by the hot-water pipes, when these were employed to keep out frost.

The tree or perpetual-flowering Carnations are now coming nicely into bloom, and are quite a feature in the house where the zonal Pelargoniums are placed

for the winter. The house has about 50° to 55° as a minimum temperature, with plenty of light and sufficient ventilation. Thrips have been rather troublesome, and a number of the best blooms are badly marked, Winter Cheer being the worst of any. The blooms of coloured Carnations are always much injured by thrips, if these insects take to them, leaving white blotches on the blooms, and when very numerous, the edges of the petals shrivel and curl up. The lively little insect did the mischief when the plants were out-of-doors, but they were soon settled by fumigation with Tobacco when they were placed inside.

THE DAHLIA.

Some few years ago I used to admire, in a well-kept villa garden, the Dahlias and Chrysanthemums flowering together up to the third week in November. I cut on October 21 last a nice bunch of coloured Primroses in our garden in the open air; also Roses and Chrysanthemums. There were also plenty of Dahlia blooms. When frost has blackened the leaves, the plants may be cut over about 1 foot from the earth, and the tubers dug up on a dry day. When dug up stand them out in the sun with the stem turned downwards, afterwards placing them in a vinery or room where they may get dried. When the tubers are well dried, store them for the winter in a frost-proof shed or cellar. If Dahlia seed was gathered, the pods may be laid out upon paper in an airy room until dry, when the seed may be cleaned from the husks.

THE GLADIOLUS.

Some of the plants will begin to decay, whilst others are quite fresh, but all may be taken up; and as they are taken out of the ground cut off the stems close to the hulbs or "corms," remove some of the soil from the fibrous roots, but be careful to save the bulblets which cluster about the base of the old corms. Spread the latter on a shelf in a vinery or airy room; and when dry cut the old corms cleanly away from the base of the new ones, removing at the same time the roots. The dried corms may be placed in bags or flower-pots, and kept in a dry place. They need not be stored in dry sand, or anything else. The bulblets of various sizes may be dried, and put into packets with a little dried sand.

Assuming that seedlings have been raised, and the leaves have died down, corms will be of various sizes, but all of them will be small, if of the present year's raising; and these may be preserved in the same manner as the above, and kept like those in some place away from frost. *J. Douglas.*

CHRYSANTHEMUMS IN GROUPS AT EXHIBITIONS.

There are undoubtedly more displays of bad taste to be seen in the arrangement of groups of this popular flower than at all the other shows throughout the season from spring to autumn put together. Some may try to explain away this defect by stating that the plants are of a more uniform character, thus making it more difficult to group a collection of Chrysanthemums than when dealing with a mixed assortment of plants. To some extent, as far as variety goes, this may be true, but it does not otherwise hold good, as may be seen when groups are compared one with the other. The fact is, that too much reliance is placed upon large blooms, irrespective of other good qualities. Cut-down plants enter largely into the composition of groups at some exhibitions. These, in combination with taller ones for the background, go a long way towards making an effective display. I have seen excellent groups thus far carried out very well, but utterly failing in the finish around the margin. In some cases the front plants are stuck upon pots, neither one or the other being hidden. In others there is a failing in the foliage, some of the front ones being destitute of leaves at the base. Some growers show plants in dirty pots; others use white sticks, when only green-painted ones should be tolerated. The sticks also in some cases are far

too stiff at the top, thus carrying the flowers in too erect a manner through their rigidity. In most groups there a deficiency of dwarf plants with which to finish off what in many a case would be a praiseworthy arrangement. Dwarf plants of about 1 foot in height are easily raised from cuttings late in the spring, and nothing adds more than these to the finish of a group. By the use of green moss, wherewith to hide the pots and the soil in the front row of plants, the effect is still further enhanced. Failing this useful material, small shoots of evergreens or anything else, so that the pots are not seen, should be brought into requisition. If it be permissible to use other kinds of plants (Ferns are sometimes specified for the purpose), by all means use them. For this purpose small examples of *Cyperus alternifolius* and its variegated form, small plants of *Carex* in var., dwarf Crotons and Dracenas (neither being chosen with too brilliant colours), the bronzy rich-looking, but not gaudy, varieties of the *Acalypha*, the light *Eulalia japonica variegata*, or *Panicum variegatum*, all add to the effect, and might reasonably be admitted as a finish to groups. They are used (or at least, some of these named) in home decoration—why not, then, in an exhibition? Another failing, one of which there will, no doubt, be a good few examples during the next few weeks, is that of too much mixing up of the colours. Perhaps three or more of one variety, and that a good and distinctive-looking one, may be used. Instead of separating these, the effect in very many instances would be far better by grouping them together. Take Sunflower or Avalanche as two examples of the Japanese section. Again, too many colours often enter into the composition of some groups, whilst in others the aim appears to be to select the very largest flowers. The former is a great mistake; it is better to have a few duplicates of the best and most distinctive kinds than to aim at variety to an excessive degree. The large flowers, it is true, go to make a show, but there is equal charm and value, with quite as much cultural skill, in those of medium size—Pompons and singles, with Anemone-flowered varieties included. Too formal an arrangement is a frequent error. In this respect, the groups usually staged at Hull and Brighton are notable examples of better taste. These are more broken up in their arrangement, tall plants being surrounded with dwarf ones, and colours grouped together with excellent finish at the front, in both places. Another common error is overcrowding; it is a stupid mistake to make, and one which seems to require a deal of unlearning on the part of the exhibitors. In many instances, the back part of a group is not sufficiently high to admit of the best display being made. If the centre be kept well up, it affords more space by a considerable extent, and is the best remedy against overcrowding. The arrangement of a group for exhibition requires some thinking out. Old hands know somewhat how to proceed, but those who are new to the work will do well to arrange their plants at home first, on the prescribed space allowed. By doing this, they will find out what to take, and what to leave at home; also what accessories are needed for the arrangement. *H.*

(To be continued.)

COMMON GARDEN INSECTS.

I. ENEMIES OF THE ROSE.—Complete success in the rearing and preservation of plants necessitates some practical acquaintance with the natural history of the commoner species of garden insects. The florist who indiscriminately destroys every form of animal life seen to invade the precincts of his garden or hot-house, is probably equally liable to suffer losses through insect ravages as his brother who entirely ignores their existence, and takes no means of protecting his plants. Many species of insects, as well as of birds, confer incalculable benefit upon the gardener. Some insects act as natural scavengers, chasing away noxious refuse; as, for example, many

of the "Necrophaga" order of beetles. Some prey upon other insects that are known to be really injurious. An example of the latter is the numerous kinds of Lady-birds and other species of insects, which in their larval condition live upon that curse of vegetation, namely, aphids, or plant-lice. Then, again, the fertilisation of some flowers is effected through the agency of bees. The common earth-worm is one of the most useful of insignificant creatures, since it is the means of aerating and fertilising the soil.

Further, the gardener who is not cognisant of some of the teachings of entomology may take tedious and ineffectual means of destroying insects, when easier and surer methods of cure or prevention are at hand. Or, again, he may go to considerable trouble and cost in destroying insects that have already laid their eggs, and have ceased to be harmful. Damage to flowers by insect-jaws is often set down to creatures which cannot eat; whilst tiny flies or moths, considered too minute or too scarce to effect appreciable injury to the most tender plant, are yet capable of destroying the hardiest tree in the country. Some innocent-looking flies are provided with veritable machine saws, with which they cut up buds and leaves, and deposit in the crevice formed thousands of tiny eggs. These quickly hatch into as many grubs possessing voracious appetites. Other flies, again, equally common-place in appearance, are the sworn enemies not of flowers, but of flower-destroyers. They alight upon the back of a destructive caterpillar, bore a hole in the body thereof, and insert one egg or more, which develop into grubs that eat up that caterpillar.

These few isolated instances are perhaps sufficient to indicate that the study of garden life is by no means unimportant to the florist from a business point of view.

We shall now endeavour (fig. 88) to illustrate a few aspects of insect history, confining our attention in the present article to some of the frequent visitors to the queen of all flowers—the Rose. We will begin with

THE LACEY MOTH,

which we have represented at fig. 1. In some seasons the caterpillar of this insect proves most destructive to Apple tree and other foliage, the Rose also being a victim of its ravages. The moth deposits its eggs generally on twig stems, neatly arranged in rows, as shown at the right-hand of our woodcut (fig. 1e). These are firmly glued together, and to the branch or leaf, by means of a natural cement applied by the mother. They are usually laid in the autumn, and the adhesive secretion forms so protective a covering for them that a certain proportion of these pretty egg-clusters withstand the frost and blasts of winter. In the following May, the first day or two of sunshine causes a change. They are seen to darken in colour; and some bright day, a few degrees warmer perhaps than the preceding one, from each a minute caterpillar breaks through its shell, like a chicken hatched in an incubator. Presently by an "unerring instinct," they club together in companies, varying from twenty to two or three hundred, and weave a common web of silk for mutual shelter and protection, under which hidden from sight, they proceed with the work of destruction. They eat, and eat, and grow; finally, attaining sometimes a length of 2 inches, but generally 1½ inch, see fig. 1c. The full-grown caterpillar is covered with long hairs; it is of bluish-grey colour, striped with blue, black, and red. When disturbed it lets itself fall earthwards by means of a silken thread, sometimes remaining suspended mid-air until confidence is restored. When the alarm is past, it climbs up by the same thread. The simplest way, therefore, to abolish these pests, is to shake the branches, and having previously spread a sheet on the ground, brush the insects into them as they fall. It is often preferable, however, to look for the webs, and gently cut them off with knife or scissors.

THE GREEN ROSE-CHAFER.

In our woodcut at fig. 2 is seen a large beetle scam-

bling on to a leaf—this is the Green Rose-Chafer (*Cetonia aurata*), a large and pretty insect, but which happens to be very destructive to Roses, Strawberries, Turnips, White Thorns, Lilacs, Elder, Mountain Ash, and some other plants. The eggs are deposited in the ground, and turn into little grubs that feed upon plant roots for no less a period than from two to three years—growing to a length of 1½ inch (fig. 2g). They then burrow further into the soil and form themselves an earthen case, covered with little pellets of earth; and, thus enveloped, they pass the pupal state (fig. 2p).

The beetle itself may be caught as it flies about in the evening; or, as it rests amongst the flowers

often so liberally distributed upon leaves, grasses, and twigs. As is generally known, each of these collections of foam hides from view a little green insect, very unhappy-looking, and sluggish when uncovered. This is the larva of the frog-hopper (*Cercopis spumaria*), which latter is represented in our woodcut at fig. 5. The perfect insect, which we have drawn as in the act of flying, is just as lively as the grub is inactive. Its little green body looks quiet enough when resting or eating, but just touch it, and it gives a sudden spring or hop into the air quicker than thought. I once took the trouble to measure the spring of a frog-hopper, and compared with its weight. I forget the exact figures, but certainly they even surprised me.

The secretion of the frog-hopper is not its only objectionable feature—in fact, this only serves as signal or sign of greater mischief, namely the hungry jaws beneath, which generally select the tender shoots, especially the axil, of Pinks, Carnations, Roses, &c.

Fortunately the larva is almost helpless when its frothy covering is knocked away—totally so, if it be exposed to the warm rays of the sun—and quickly dies. This fact should be borne in mind in combating its ravages. We have found an excellent cure is that of carbolic acid. A few teaspoonfuls of the common liquid acid in a gallon of hot-water, and when cold, the plants watered therewith, immediately kills cuckoo-spit larvae, also blight, and many other minute pests. We have found this treatment to be quite innocuous to the flowers, and have saved scores of Rose trees by its means. We needly hardly warn our readers that this acid is a deadly poison, except in excessively dilute solutions, and requires the utmost care in its employment.

THE MALE OF A DESTRUCTIVE INSECT, THE WINTER MOTH,

is shown at fig. 3, just beneath the branch. Its caterpillar is of bright green colour, and always closely resembles in tint the leaves which it eats. It is of the "looper" kind, and walks by arching its body, and bringing the rear part up to the fore part. When disturbed it lets itself down by a thread. The female winter moth is devoid of flying wings, possessing only an apology therefore in the shape of a diminutive pair of useless undeveloped wings. It has, however, long and agile legs. When it emerges from the pupa condition, which is passed in the ground, it nimbly climbs the trunk or stem, and amongst the foliage deposits its eggs. Hence, this is the point at which its progress must be stopped. This is easily done by applying with a brush round the trunk a band of some sticky composition, such as cart-grease or tar. This should be done in April and May, and again in October and November. The moth, if no such preventive is adopted, on reaching the branches, lays her eggs during the night-time on almost any part of the plant—fruit, leaves, buds, or bark. They are of microscopic size, green in colour, and difficult to detect, and are firmly secured by means of natural gum. In spring, the grubs are hatched, and at once attack the young buds, calyces, &c. They become mature about November, or a little earlier, and let themselves down to the ground, and, burrowing some little depth, become chrysalises, turning into moths before spring arrives.

It may not be out of place here to remind fruit-gardeners that many species of injurious insects choose the ground at the foot of trees wherein to undergo the transformation from larva to pupa. During the winter, we frequently dig up scores of pupae from the foot of a single tree, and so save the deposition of thousands of ova in the spring time.

THE MOTILED UMBER MOTH

is represented in our woodcut at fig. 4, which is also a winter flyer, as indicated by its scientific name, *Hybernia defoliaria*. Its habit and metamorphoses closely resemble those of the last-mentioned moth, and a like remedy is to be adopted for its eradication. The female is entirely destitute of even the rudiments of wings, and few people not entomo-

FIG. 88.—COMMON GARDEN INSECTS.

during the afternoon. It generally selects the petals and stamina of flowers to eat.

We regret that we can give but a slight idea of the appearance of this beautiful beetle by our non-coloured drawings. It is of a brilliant green, and in common with the majority of beetles, has a metallic lustre, frequently exhibiting a golden or coppery hue; the elytra or wing-cases also are spotted irregularly with white. The eyes are rather large, and project; the head is thickly punctured; the horns are short, ten-jointed, and clubbed at extremity; and on each side of the insect is a prominent sharp spine.

"CUCKOO-SPIT," AND WHAT PRODUCES IT.

Few products of insect-life are more unsightly than those little masses of white frothy matter, known as "cuckoo-spit," or "frog-spit," which are

logically informed would suspect the relationship between it and the winged sex.

A famous naturalist once asserted that fully 200 distinct species of insects preyed upon the Oak. I would not venture to guess how many attacked the Rose, but it would be easy to demonstrate that there are sufficient to render it desirable to afford the plant every protection possible against its natural foes. *Frank Young.*

(To be continued.)

FORESTRY.

THE COMMON HORSE-CHESTNUT, *ESCLUSUS HIPPOCASTANUM* (L.).

This fine ornamental tree is thought to be indigenous to the Levant and other places, and is supposed to have been introduced into this country about the middle of the sixteenth century. It is thoroughly hardy in Great Britain and Ireland, and when fully established its contour is that of a large round-headed tree of great substance, and when loaded with its large and beautiful flowers in early summer, it has no rival in this respect as a first-class specimen tree for embellishment. Soil and climate, however, seem to exert a marked influence on its growth and appearance, as we sometimes find the trunk to exhibit a spiral or twisted appearance, while the foliage presents different tints of colour in autumn.

At Churchill, co. Armagh, Ireland, there is a medium-sized tree growing on the edge of a peat bog, whose foliage at the top gradually exhibits a reddish colour about the month of July, and by autumn the leaves at the very top are of a deep scarlet colour, which makes a fine contrast with other trees in its vicinity. The site of this tree is only about 80 feet above sea level, and it produces great abundance of fruit every year. But the tree is by no means confined to low-lying situations, as it attains a large size in the highlands of Scotland at an elevation of 1110 feet above sea level. At Invercauld House, Braemar, Aberdeenshire, there is a tree of this species upwards of 110 feet high, and contains upwards of 100 cubic feet of timber. It produces great wealth of flowers every year, but I have never known it to mature fruit at this elevation. At Abergeldie Castle, in the same shire as the above, there is a nice round-headed specimen of the Horse-Chestnut; it stands on the lawn right in front of the Castle, at an elevation of about 800 feet—the soil is gravelly loam. These examples show that the tree is thoroughly hardy, and well adapted for the climate of this country. But the Horse-Chestnut often exhibits great variety in shape. Sometimes we find the contour of the tree to be tall and conical, while others form a globular head as exact in form as if cast in a mould; others, again, form enormous spreading heads with the larger branches, or rather limbs, resting upon the ground, which prevents them from being torn off the trunk by their immense weight. Many years ago, when assisting to overhaul and renovate the grounds at Skene House, one of the seats of the Duke of Fife, in Aberdeenshire, we came in contact with a large spreading tree of this type, and as some of the large rambling limbs interfered with the carrying out of other improvements in their vicinity, they had to be cut back, but the space still occupied by the branches was 90 feet by about 70 feet. Some twelve of the larger size of limbs rest upon the ground, and afford ample space and accommodation for a large number of people to assemble around its trunk and below its canopy of verdant foliage. The height of this tree is about 58 feet; the elevation of site above sea-level, is 350 feet; soil gravelly loam, resting upon gravelly clay. When the leaves of the Horse-Chestnut begin to expand in early summer, the growth of young wood at the terminal points of the branches and twigs start to grow at the same time, and is generally perfected for the season in about a month's time, and that peculiarity of growth gives it time to ripen and mature its young wood by winter, which, in a great measure, accounts for the

hardiness of the tree. When the wood is cut up for use, it is found to be of a light, soft texture, on which account it cannot be recommended as a timber tree for general utility, yet when the wood is seasoned, it is capable of being used by the turner and cabinet-maker for a great variety of purposes in connection with his craft. The tree is generally propagated from its nuts, which ripen in autumn and fall to the ground, and are then apt to be eaten by sheep and deer. The nuts may either be sown at once, or at any time during favourable weather in winter, either in drills or broadcast on seed-beds 4 feet wide; one bushel of nuts should be allowed for 20 lineal yards of a bed the above width. Press the nuts down on the surface with the back of a spade or roller, and finish by covering them to the depth of 1½ inch of fine soil. When gathering the nuts for this purpose, the largest sizes should be selected, as they produce by far the best plants. The seedlings will grow in any ordinary soil, but a deep loamy one, rich in organic matter, produces by far the best and largest plants.

There are several varieties of this tree in cultivation, one of the best of which is *E. rubicunda*, which is of a lesser size than the species, and makes a nice specimen tree for a small lawn. The flowers are of a red colour, and produced year after year in the beginning of June in great abundance. Another peculiarity of this variety is, that it commences to produce flowers during the early stages of its growth. I have had trees loaded with flowers when only 10 feet high. The fibrous roots of this tribe of trees render them suitable for transplanting with safety after they have attained a pretty large size, which is also a recommendation in their favour; and amateurs and others, when planting their grounds at suburban villas and elsewhere, should keep this in view. The Pavia or Indian Chestnut tribe of small trees, of which there are several varieties, are also well adapted for this kind of planting. The Pavia flava is a yellow variety from California, and is a charming small tree for a lawn; in autumn the foliage exhibits a richness of colours which is not surpassed, if even equalled, by any other tree at that season. *J. B. Webster.*

CHRYSANTHEMUM JOTTINGS.

(Continued from p. 555.)

ROYAL EXOTIC NURSERY, CHELSEA.—The firm of J. Veitch & Sons is famous for so many things that we may be sure the finest of autumnal flowers finds a place in the floral display at head-quarters. A good-sized span-roofed house contains the pick of the collection, which consists of about 1000 plants in the most select variety.

We may say that only the best are represented, and these show this year better culture than we remember to have observed on former occasions—blooms larger generally, foliage finer and stouter, and growth sturdier. Amongst novelties, mention should be made of the following:—Mr. H. Ballantine, a yellow, hairy, incurved Japanese; Bouquet des Dame, white, of the same class as the preceding; Florence Davis, greenish-white; W. K. Woodcock, a flower coppery-brown, of good substance, a very enduring flower, either on the plant, or when removed from it; Mrs. Robinson King, canary-yellow, incurved Japanese, with broad florets; Colonel B. Smith, twisted, recurring florets, bronzy-coloured, the florets tipped with yellow; W. Tricker, an introduction of last year; Gloire du Rocher, same year; H. A. Neve, a nice reflexed light pink Japanese; Mlle. Marie Hoste, a Japanese, with broad florets of flesh colour, changing to white with age; Miss Anna Hartshorn, the best white Japanese variety; Mlle. Lacroix, a thread-petalled Japanese, yellow, of the shade of the older variety of that name; W. A. Manda, E. Beckett, a rich yellow flower, that is usually excellent; Miss Judge Benedict, the finest Anemone-flowered variety extant, yellow disk, and pink or white guard florets.

Besides the Chrysanthemum plants in the span-house are others of fine quality in the long Camellia-

house that forms the nursery entrance from the Fulham Road.

MR. DAVIS'S NURSERY AT CAMBERWELL.

Mr. Norman Davis has long been known as a Chrysanthemum grower, and a successful one. A visitor to the nursery in Lilford Road will see many new and good varieties, and some good blooms of older kinds. Like most other growers, Mr. Davis complained that his plants are rather later this year than usual, but they all look healthy, and promise a rich display. Pouring with rain as it was when we were at Camberwell, the scene in the house where those in bloom were grouped, offered a pleasing contrast to the dreary appearance outside. The first variety to attract attention was Florence Davis, which was raised here about two years ago. Some fine blooms as seen here, created a more favourable impression than had this variety hitherto. It is so perfectly distinct, and presents such a pleasing appearance just when passing from green to white. Miss Watson is a new Japanese of pleasing lemon-yellow, and a few yards away are some good blooms of Felix Cassagneux, a variety very like Bismarck, brought out some two years or so ago. Madame Ed. Rey, a Japanese raised by Calvert in France, has large heavy blooms, and is a good thing. The top of the bloom is a pretty cream-colour, and the lower petals are of rose. The lovely-coloured Wm. Tricker is again in evidence, and some good blooms of Geo. Savage, the new Japanese incurred, much after the style of Anna Hartshorn. Another very pretty creamy-white Japanese, called Diane, was in nice bloom, and a good stock of Colonel W. B. Smith, promise some good blooms. A large number of plants of Viviani Morel and W. H. Lincoln are grown in 48's for grouping; they bear one bloom on a plant, and are well clothed with foliage down to the pots.

AUTUMN-SOWN PEAS.

SINCE the extensive use of glass in gardens, many gardeners have ceased to sow peas in the autumn, and sow the earliest crop in small pots, on pieces of turf, or in wooden troughs, placing these in a cool house in January. The plants are grown on under glass, with plenty of air until favourable weather occurs in March for planting them in the open quarters, and good crops are to be obtained in this way if care be taken to protect the plants from severe frost and cutting winds when they are first put out. But I consider it much easier to sow Peas outside in November on the old-fashioned plan, and take care of them during the winter. If they do not come up well, or any misfortune occurs to them, there is then still the opportunity to make good any loss by sowing seed under glass. This is the method that I always adopt, and invariably get good crops. The ground is got ready a month before sowing time, choosing a warm piece of land open to the south, and, as far as possible, sheltered on other sides. This receives a good dressing of farmyard manure, which is dug in deeply, and the soil left to settle, and on a dry day, about November 5, or soon after, the seed is sown, thicker than is usual for spring sowing, and covered in level with the surface. On the top of the soil we put about 1 inch of sifted coal-ash, covering the soil about 9 inches in width, which prevents frost penetrating the ground so deeply as it otherwise would, and also checks the ravages of slugs, &c., after the Peas come up. Mice seldom give us any trouble, but we keep a good watch for them, as they soon do a lot of mischief. A good cat or two constantly about the garden is the best remedy, and next to this is trapping with Colin Pullinger's perpetual traps, or the old-fashioned figure 4 trap. After the Peas get through, it is a good plan to scatter a few fresh ashes along the rows as the first lot will have got somewhat solid; and if there is any danger of frost or cold winds, branches of evergreens are placed along the side that is most exposed at a short distance from the young plants, and in very cold springs we replace these for a time after the Peas are staked; but before the latter

operation takes place, we remove as much of the coal-ash as can conveniently be done with a shovel, and with a rake, draw some soil up to the plants to take its place, as I find the coal-ashes are apt to set together in a hard mass, preventing the rain from penetrating to the roots.

After trying all the so-called earliest varieties, I now rely upon Laxton's Earliest of All for the first few dishes, following it with Laxton's Standard, a variety that has almost gone out of cultivation. Standard is a heavy cropper, of better quality than the ordinary early round varieties of Peas, and stands the winter here better than any. After this comes Ne Plus Ultra, which is the favourite Pea for the best table; but many gardeners consider this variety of no use for autumn-sowing; but, as a rule, I find it does well, if treated as I have described. Last winter we had the thermometer at zero-point twice, still, the Pea crop was a heavy one. It is very

ZONAL PELARGONIUM,
MR. GORDON.

For summer, and especially for winter blooming, no plant has surpassed the Pelargonium in producing a floral display, at once acceptable to the florist and to the ordinary lover of flowers, innocent of any of the florists' arbitrary methods of looking at things. The subject of our sketch (fig. 89), is the variety Mr. Gordon, and it is due to the kindness of Mr. Comfort, fr. to G. A. Everitt, Esq., Knowle Hall, near Birmingham, that we are enabled to reproduce it. The plant was photographed in August, and at that time measured 4 feet in diameter, and bore 165 trusses of bloom. P. Mr. Gordon is a beautiful rich crimson, with a pure white eye, and, when grown to perfection, forms a very lovely object indeed. The culture of this plant is simple, and is understood by most gardeners, but it is only by thorough attention to the details concerning same that the highest success can be obtained. On Tuesday next, at the meeting of the

man, who is now the champion Tea Rose grower, that in the days of his "babyhood" he went to see the garden at Canton Manor, which the present Dean of Rochester (then Canon Hole) had made famous; he came away with the conviction, which he formed at the time, that all his Tea Roses were dead, and so to his unpractical eye they appeared. But their owner afterwards assured him that they were all very much alive. Again, I recollect asking one of our most successful rosarians in Cheshire why he did not grow Teas out-of-doors (he had a grand lot under glass)? "Oh! impossible in this climate," I, however, persuaded him to try; and the last time I saw his garden, he pointed with some satisfaction to a bed of vigorous Tea Roses, which he called my bed. I have had Teas, too, from Messrs. Cocker & Son, at Aberdeen, which were as vigorous as any grown in the south; and it is a "far cry to Aberdeen." I am therefore strongly of opinion

FIG. 89.—ZONAL PELARGONIUM, MR. GORDON: CRIMSON, WITH A WHITE EYE.

necessary, however, to get new and well-ripened seed of this variety, or it will refuse to germinate so late as November, and for this reason I always save seed for this sowing whenever it is possible. This season we gathered the first dishes of the above kinds as follows:—Laxton's Earliest of All, June 4; Standard, June 15; Ne Plus Ultra, June 22; these were sown November 14. We were not able to sow in the spring until March 21, and the first dishes of this sowing were ready as follows:—Duke of Albany, June 26; Criterion, June 29; Ne Plus Ultra, July 18; Success, July 23; Veitch's Perfection, August 5; of these, Criterion is not good enough in quality, although a good cropper, and I shall not grow it again; Veitch's Perfection is too long before it comes into use, and although of good quality, is not now required; Success I like very much, it is a distinct Pea, crops well, and is excellent when cooked. *W. H. Divers, Ketton Hall Gardens, Stamford.*

Royal Horticultural Society at the Drill Hall, Westminster, Mr. Pearson, of Chilwell, Nottingham, is to give a lecture on the "Culture of the Pelargonium for Autumn Flowering," and we will not anticipate this lecture by going into the details of management now.

THE ROSERY.

THE ROSE-GARDEN IN OCTOBER.

TEAS AND NOISSETTES.—Although the treatment of these beautiful classes in autumn is in some respects similar to that for hybrid perpetuals, there are some differences; at least, it must be so in some parts of the country. There is a common belief that Tea Roses are less hardy than hybrids. This may have been the case formerly when they were grown on standards, half-standards, and Mauetti. I do not think it is so now, when they are grown as dwarfs, budded on the seedling Briar. It is related of a gentle-

that they may be grown almost anywhere where hybrids succeed. Of course, there are some delicate growers amongst them, but so there are amongst hybrids. Some few people can grow Horace Vernet or Xavier Olibo for example a second season, and some of the hybrid Teas such as Lady Mary Fitzwilliam are most difficult to keep.

In preparing Teas for the winter, I do not thin out the old flowering brood as I do the hybrids; in fact, they are such late bloomers, that it would be a pity to do so. I have to-day (October 24) gathered even from my small collection, quite a handful of beautiful blooms; moreover, as I generally cut them nearly as hard as H.P.'s in the spring, it is hardly necessary; and what the grower expects is, that strong shoots will spring from the base of the bush, and grow rapidly, producing a large quantity of flowers. If the weather is severe, the frost will act as a pruning-knife, and under the circumstances, I leave the Teas very much as they are at the present time.

I think that they do not require so strong a soil as the hybrids, and where new beds have to be prepared, I would trench the beds in the same way; and where the soil is heavy, and the situation damp, I would raise the beds a few inches above the level, as recommended by Mr. Geo. Paul in the *Rosarian's Year-Book*, much in the same way as the "lazy beds" of the Irish peasant are prepared for Potatoes; this allows superfluous water to drain off.

There will be vacancies to be filled up in beds which have been previously planted, and the question is, what to plant. Were I writing for exhibitors, I would say plant half-standards, for it is almost universally stated that on these the best blooms for exhibition purposes are produced; but as I am rather writing for the general lover of Roses, I would not recommend them, but to obtain dwarfs on either the seedling Briars or Briar cuttings. You must protect half-standards, and if the winter be a severe one, you must expect many to be killed, whereas there is always a fair chance of your dwarfs surviving the severest winter. In the same way, with regard to the varieties to be used, either to replace those, the same considerations must guide one in those which I recommend. It is of little use, I think, recommending flowers which, although very beautiful when you get them, are so apt to be spoiled by wet that the chance is a rare one. Take such a flower as Jean Ducher, or in a less degree, that most lovely flower, *Souvenir d'Elise Vardon*—when the weather is wet, the blooms are glued together, and never open, so that not only is there disappointment but an ugly appearance in the garden. There are a few which are difficult to grow, and one or two of these are so lovely, that notwithstanding their delicacy of constitution, they must be included. For instance, there is that most lovely, as I think, of all Teas, *Comtesse de Nadaillac*; it is delicate, but then its colour is so exquisite and form so perfect, that one cannot exclude her. There are, again, others which are not show Roses, but which are delightful for the garden; such a Rose is *Homère*, strong and vigorous, with flowers exquisitely bordered with pink, but small, and not of first-rate form. In *Ma Capucine*, one of the most exquisitely-coloured Roses we have in the bud, we have a flower so very thin that it soon opens. In the following there are those, I think, which may be safely relied upon as good flowerers and vigorous growers:—

Alba Rosa, as *Madame Bravy*, white, with flesh-coloured centre, very free-flowering.

Catherine Mermet, flesh colour, beautiful form, and very free.

Anna Olivier, rosy-flesh, base of petals deeper sometimes in some localities, assuming an orange tint, which is very attractive.

Caroline Kuster, bright lemon-yellow, very free, and at times most beautiful.

Comtesse de Nadaillac, the most beautiful, I think, of all Teas; the colour an endurable mixture of apricot-yellow, flesh colour, rose, and copper. Not a vigorous grower, but one that cannot easily be dispensed with, even with that drawback.

Hon. Ethel Brownlow, salmony-pink, with copper shading—a very beautiful rose; something in colour like *Madame Lambard*, but much better in form, and brighter in colour.

Francisca Kruger, coppery-yellow, shaded with peach. Large, and very free-flowering.

Homère, one of the hardest of Tea Roses. Colour, rose, with salmon centre; edges of petals marked with pink. A very attractive garden Rose.

Hon. Edith Gifford, light flesh, very slightly tinged with salmon.

Innocente Pirola, creamy-white, sometimes slightly tinged with flesh. A most free-flowering hardy Rose.

Ma Capucine, small and thin, but very lovely in the bud.

Madame Charles, deep apricot yellow.

Madame Chodum Guivoisseau, a small button-hole Rose; pale canary-yellow.

Madame Casin, rose, with lighter centre. A very good and free-flowering Rose.

Madame de Watteville, a very beautiful, but somewhat delicate Rose. Salmony-white centre, the petals are bordered with light pink. Very attractive.

Madame Falcot, a brilliant deep yellow Rose, with too great a scarcity of petals to make it an exhibition Rose, but an abundant bloomer, and a capital garden Rose.

Madame Lambard, a very hardy, vigorous, and free-flowering Rose, varying much in colour, from yellow to red, and very often on the same bush will be found blooms as different as possible. Becomes much deeper in autumn.

Perle des Jardins, vigorous, free-flowering, with beautiful foliage, but the buds are very apt to come quartered.

Souvenir d'Elise Vardon.—Perhaps this Rose has taken more medals than any other Tea, yet, withal, I do not advise the amateur to have much to do with it, as it is so very full that in wet weather it all clings together, and does not open. In a fine hot and dry summer it is a grand Rose.

Souvenir de Paul Neyron, creamy white, with delicate tint of flesh in the centre. A very attractive flower.

The Bride, almost white. An American sport from Catherine Mermet, and a most beautiful flower.

Souvenir de S. A. Prince, a white sport from *Souvenir d'un Ami*, and equally desirable. There are some who do not care for these round Teas, but prefer those with pointed buds.

I have omitted from this list high-coloured flowers, because I do not personally care for such flowers as *Souvenir de Thérèse Levet*, *Princesse de Sagan*, and *Marquise de Vivens*, they take away the delicacy of colouring which I think is one of the chief charms of the Teas. Nor have I included the newer Teas; but those who wish to grow such will find in *Madame Hoste*, *Ernest Metz*, *Cleopatra*, *Sappho*, and *Waban*, valuable additions to their beds.

Although I have called these notes "The Rose-Garden in October," the weather has been so wet that I fear very little can be done this month. Nurserymen do not care to execute their orders, and while the ground is in the state it is, it will be much better to defer planting, hoping for a more favourable time. When the beds are planted, then the winter protection must be prepared. The best plan is to throw up some of the soil from the beds around the collar of the plant, and then place all over the beds a coating of 3 or 4 inches of stable-yard manure, not hot, nor too much rotted; this to remain all the winter, until all its best properties are washed down into the soil. Where Tea Roses are much exposed, a few Bracken fronds will keep off the more severe weather; but I never think of doing anything of this kind, and growers must be governed by the special circumstances of their situations.

Wild Rosa. [Our correspondent sent his notes to us in October, but the pressure of other matter prevented their publication. Ep.]

THE WEEK'S WORK.

THE ORCHID HOUSES.

By H. A. BURBERRY, *Orchid Grower, Highbury, Birmingham.*

THE COOL-HOUSE.—Of Orchids of recent introduction, *Cochlidia Noetziiana* is, perhaps, the most fascinating. We have now seen the flowers produced from fairly strong pseudobulbs, and there no longer remains a doubt of their beauty and usefulness. It is satisfaction to know that the glowing descriptions respecting the merits of this pretty little Orchid have not been exaggerated. I think the spikes and flowers will never attain to the size of *Odontoglossum Pescatorei*, yet when new pseudobulbs have been made equal in size to those naturally grown, no doubt the spikes will be much more branching, and the flowers proportionately larger. The colour, which is a lovely shade of scarlet, considerably adds to the attractiveness of this species. Although rather slow to establish itself, it is generally pretty sure to grow, as very few of the newly imported pieces actually fail to start, and each year the new pseudobulbs get larger and larger; this fact, together with the hard, healthy appearance of the same, suggesting easy culture when really established. As this is a small-growing Orchid, I would recommend that it be not over-potted, rather using

small earthenware pans or Teak-wood baskets, and suspending them near the roof-glass. In the same manner, should the pretty little *Occhidium Phalaenopsis* be grown: it is an easy matter to get too much compost round the roots of these small-growing species, which, when watered, remains soddened for a much longer time than it should. Any of the *Occhidiums* or *Odontoglossums* that are sufficiently advanced in growth to produce spikes, should be elevated on stands, where they can be watched, otherwise the chances are that a slug will be the first to find out the young tender flower-spikes. *O. Phalaenopsis* during winter requires the warmth of the intermediate-house.

DENDROBIUMS.—For the welfare of the plants, I have advised that they should have a long rest, and not be hurried into flower; if, however, a few are required for Christmas blooming, such as *D. Wardianum*, *D. nobile*, and *D. Ainsworthii*, the earliest should be selected now, and placed in the intermediate-house, where the gentle warmth and moist atmosphere will be all that is necessary at the commencement. It should be borne in mind, that if *Dendrobiums* be subjected suddenly to strong heat or too much water at the roots, the flower-buds will either drop or turn to growths. As regards top-dressing or re-potting *Dendrobiums*, it generally happens that the plants after flowering are more or less in active growth; and at that time also other work is pressing, making it almost impossible to give the *Dendrobiums* such careful handling as they should have, so that everything that can possibly be done now to forward this work should be done. It is a wise plan before starting *Dendrobiums* with a view to flowering them, to trim off aged and withered pseudobulbs, to well clean those remaining, neatly re-tying them to new sticks, and to top-dress or repot, as the case may demand, using good sphagnum moss entirely, rather than peat of any but the best quality. This will save much time at a later date, and the plants receive no further check to their growth.

THE FLOWER GARDEN.

By H. W. WAARD, *Gardener, Longford Castle, Salisbury.*

BANKSIAN ROSES.—These popular climbing Roses should be given a warm situation, and allowed plenty of room to develop, that they may show off to the best advantage their small globular white and yellow flowers. The varieties are:—*R. Fortunei*, white, large-sized flowers; *Jaune Serin*, very rich yellow, with fine foliage; *alba*, or white (the old variety), small white flowers; *lutea*, or yellow (the old variety), fine yellow flowers, small and full.

MINIATURE, OR FAIRY ROSES.—These diminutive Roses are well adapted for pot-culture, or as edgings for Rose-beds, and for planting in small groups of from five to nine plants in herbaceous borders. In a cut state, the clusters of tiny blooms are very useful for vases, and for bouquets. The best varieties are:—*Anne-Marie de Montravel*, flowers very small, of the purest white, a perfect "Fairy Rose," and deliciously scented; *Lawrenciana rubra*, the old double red fairy, free-flowering, and very pretty; *Mignonette*, soft rose, changing into white, very beautiful; *Paquerette*, pure white, very continuous and pretty; *Perle d'Or*, yellow, with orange centre, flowering in large clusters, novel and distinct, and very pretty in the bud-state; *The Pet*, double white, profuse bloomer, and one of the prettiest little Roses in cultivation.

CLIMBING EVERGREEN ROSES.—To be correct, the so-called evergreen Roses, which have originated from *Rosa sempervirens*, are only sub-evergreen, retaining their leaves till the approach of spring. They are well adapted for covering pillars, arches, and banks, being vigorous growers and free bloomers. The shoots should be well thinned in pruning, and left nearly their full length, merely cutting off the weak points of the reserved growths. The varieties here recommended are:—*Adelaide d'Orléans*, white; *Banksiaeflora*, white, centre pale yellow, small flowers; *Dona Maria*, pure white, small; *Félicité Perpétue*, creamy-white, flowers small, full and beautiful; *Leopoldine d'Orléans*, white, shaded with rose; *Princess Mary*, reddish-pink; *Princess Louise*, blush; *spectabilis*, rosy-lilac, large and double.

PLANTING TREES AND SHRUBS.—Where the making of beds and borders of ornamental trees and shrubs is contemplated, the work should be pushed forward quickly, with a view to getting the planting done before frost sets in. The borders, if new, should be slightly or boldly irregular in outline, according to the size of them, and the beds should

be of simple shape, irregularly but gracefully curved. The land should be trenched or dug two spits deep, and if the under-soil be of good quality, it may be brought to the top; but where the soil is shallow and poor, leaf-mould, road-scrappings, and such like should be added after it is dug, mixing these materials with the staple when planting. In the case of the natural soil being stiff and heavy, wood and coal-ashes may be applied in addition to the other substances, which render it more congenial to the requirements of trees and shrubs generally. I may here remark that Rhododendrons and Azaleas will do fairly well in soil of the latter description, and still better if a few shovelfuls of peaty soil be placed about their roots. If leaf-mould be plentiful and peat less so, it may be used instead.

GENERAL WORK.—This will consist in daily sweeping and removing the fallen leaves from walks, lawns, and pleasure-grounds, so as to preserve good order in every section of this department.

THE KITCHEN GARDEN.

By G. WYTHES, Gardener, Syon House, Brentford.

TOMATOS.—If the plants are grown in numbers to afford a constant supply of fruits during the winter, the blossoms should have been fertilised in September and October, these not setting well at a later period. Assuming that the number of fruit secured is sufficient for all demands, there is less difficulty in getting the fruits to ripen if the house is a suitable one for Tomatos. Free ventilation should be afforded in fine weather, and a small amount of air by the upper ventilators during the night; the temperature may now reach during the day 60° to 65°, and at night 50° to 55°. The plants should have every ray of light, and be supplied with some kind of stimulus to growth. The house should be freed of undue moisture before nightfall, and root-watering sparingly done. With an increase of temperature, insect foes will increase also, and these must be kept under by means of a light fumigation once a week, which will be sufficient to prevent the white-fly increasing in numbers. Spring fruiters should be kept gently on the move, and near the glass, so as to ensure a sturdy growth. The temperature for these plants may be 55°. Keep the unnecessary shoots of these later fruiters stopped, and allow them ample room to extend.

FRENCH BEANS.—If these were raised in frames early in the autumn, and are now showing pods; the plants will need a greater degree of warmth, and if the pots are full of roots, tepid, weak liquid-manure may be afforded the fruiting plants. Beans do well on stages or shelves near the roof—in such positions the blooms set better. A sowing of French Beans may now take place if proper forcing-pits exist, which will afford a few dishes if the weather be favourable. Failing the proper appliances, sowing had better be deferred to the beginning of January.

MUSHROOMS.—The early-made beds should now afford a supply, and the temperature of the house not exceed 55°, or the life of the beds will be short. The covering of litter should be removed when the Mushrooms begin to appear, and when the soil of the beds becomes dry, water it with tepid water. Fresh material may be prepared, and new beds made, spanning them when the heat in the bed declines below 90°, and covering them with loamy soil warmed to 90°, making this covering firm, but not, as is often done, so that the Mushrooms cannot emerge.

SALADS.—Plants of Endive should be lifted when dry, and blanched in some dark place. Chicory roots should be similarly treated, but affording these a little warmth—say 55° to 60°. Mustard and Cress, if required daily, should be sown at fortnightly intervals, using shallow boxes and light soil. Sow the seed on the surface, and gently press it into the surface, covering with a slate till the seed sprouts. No water will be required if the soil be moist.

FRUITS UNDER GLASS.

By J. RIDDELL, Gardener, Castle Howard, York.

VINES.—During the next eight weeks an examination of all bunches must be made every few days for bad berries, cutting out any that show the smallest signs of decay; especially, should the centres of the bunches be well examined, the inner berries usually being affected before those on the outsides. All leaves which readily fall at the hand's touch should be removed at the same time. Maintain a temperature in theinery in which Grapes are hanging of 45° or 50°, and always keep the hotwater-pipes or flues

slightly warm. At this season much judgment must be exercised in affording air, as it sometimes happens that the weather is mild, and the atmosphere charged with moisture. On days of this kind the ventilators should be kept closed, the artificial heat very slight. In bright dry weather, however, air may be admitted to the houses by opening only the top ventilators. The dry atmosphere, so essential to the proper keeping of Grapes, soon deprives the border of moisture, and renders frequent waterings necessary to keep the berries plump, and this although heavy mulching may have been afforded to reduce evaporation as much as possible. To avoid loading the air of theinery with moisture, a sunny day with a dry wind should be taken advantage of, to afford the borders a good watering, and at the same time keeping a brisk heat in the heating-apparatus, and the ventilators open, to carry off the moisture as much as possible before nightfall, and afford as much ventilation as is prudent during the following days.

POT VINES to be early forced, should now be got in readiness for starting them. If they were cut back to the required length advised in a former Calendar, no more pruning will be necessary; but in cases where this has been omitted, a shortening of the canes should be made at once, or what is known as bleeding may occur when the Vines are placed in heat shortly after the pruning. Although the canes may be regarded as clean and free from injurious insects, it is better to err on the side of extra precaution by cleansing them with a soft brush and Fir-tree oil. Remove as much of the surface soil in the pots as can safely be done; and the best tool for the purpose is a piece of sharp-pointed iron rod, half an inch in diameter. Having removed the upper crust of soil, afford a surfacing of loam, horse-droppings, finely-broken old mortar, and some of Thomson's Vine Manure, all well mixed together, and make this compost quite firm by ramming it with a blunt rammer. The plants may then be stood in a cool-house until put into the forcing-pit. I have never found it necessary in keeping up a supply of Grapes all the year round, to commence forcing before the beginning of the month of December, but where it is intended to make an earlier start, a hot-bed should be got together, for the purpose of supplying bottom-heat and moisture, if the structure favours such means being adopted. In this bed plunge the pots to their rims, and incline the ends of the canes downwards to check the flow of sap, thus fostering an even break. Failing a hotbed, stand the pots on or over hotwater-pipes, with a tray to hold water beneath them, but in which the pots should not be placed. Keep the canes moist, and give them a minimum temperature of 50° to start with.

PLANTS UNDER GLASS.

By R. MILNER, Gardener, Penrice Castle, Swansea.

CYCLAMENS.—The earliest of these should be in bloom about this date, and the plants, if carrying good heads of flowers, will be the better for an occasional application of weak manure-water. A low structure, where the plants can be stood well up to the glass, is best for Cyclamens, the night temperature being kept not lower than 50°, with a rise of 5° to 10° by day, according to the amount of sunshine. Give heed that damp does not injuriously affect the flowers, and to avoid risks, admit a good volume of fresh air when the outside temperature is favourable for so doing. Thrips do much harm, but occasional fumigation with tobacco in some of its forms, before the blooms expand, will greatly lessen the number of these insects. Seedlings strong enough to be potted off singly into thumbs or small 60's, should have attention, employing a potting soil consisting of two parts rich loam, and one each of leaf-soil and peat, with a little rotted and dry cow-dung, which has been reduced to powder, and sufficient sharp sand to keep the soil porous. Grow the plants steadily on, never allowing them to feel drought at the roots, or they will be checked seriously, an error to be carefully avoided by the would-be-grower of fine plants.

THE WARM CONSERVATORY.—It is during the short gloomy days that the conservatory is most valued; and where the heating apparatus of the house is sufficient to enable flowering plants to be placed therein, it is doubly so. But without sufficient heat, it would not be prudent to place in it forced plants, i.e., when the temperature falls below 50°. The conservatory should be the pink of cleanliness in every part, the pots, tubs, paths, glass everywhere; and decayed leaves and flowers past their best should be removed daily, and the plants grown for their

foliage should be frequently cleaned with a sponge and clean water, and insects hunted out and destroyed. Any walls which are masked with Ferns, Begonias, Selaginellas, Panicum variegatum, Tradescantia, &c., should be inspected occasionally; and at this season of the year water should be sparingly afforded or the plants may suffer, and decayed fronds, leaves, &c., removed, so that this portion of the structure may look pleasing to the eye.

The following subjects will be found useful to intermix amongst those which are either planted out in the borders and beds, or growing in pots, viz., Plumbago rosea, P. coccinea, the winter-blooming Begonias—mostly fibrous rooted, such as B. nitida, B. John Mease, and B. insignis, &c.; Linum trigynum, a pretty plant at this season, either in pots or planted out, the latter being, in my opinion, the better method of growing it, as red-spider is then less troublesome. Flowering plants of Calanthe vestita rubra and C. Veitchii may also be brought to the conservatory, and intermingled with Ferns and other foliage plants. The soil in which the Calanthes are growing must not be allowed to become very moist, or the plants will suffer. Gesneras are telling plants at this season, also Eranthemum pulchellum, Cypripedium insigne and its varieties; and Scutellaria Mocciniana; these, with plants of Euphorbia Jacquiniaeflora, Eucharis amazonica, Lily of the Valley, Poinsettias, and Primulas, will make a fine display.

THE HARDY FRUIT GARDEN.

By H. MARKHAM, Gardener, Mereworth Castle, Maidstone.

PLUMS.—The finest varieties are produced by wall trees, and when these are well cultivated, there is no more valuable fruit than the Plum. Only varieties should be planted which are the best of their various classes; and any fairly good soil will grow them well, provided some small amount of lime is afforded from time to time. The wall-tree borders should be well made and drained if the land is retentive, and they should be made, if of good soil, of not less depth than 2 feet; on light gravelly soil, 3 feet will not be too deep. West and north aspects suit them admirably, and by planting on both sides, the season is greatly prolonged. In selecting dwarf-trained trees, the stems should be from 12 to 18 inches high, the same as for Peaches, Apricots, Cherries—indeed, for all trees which will be trained in the fan form. Plum trees should be planted 15 feet apart, and as these grow rapidly, supernumerary trees need not be planted between them. Of varieties to plant we may mention the following:—August: Early Orleans, Rivers' Prolific, Oullin's Gage, Golden Gage, Belgian Purple, Denniston's Superb, and Sultan. September: Jeyfer's Victoria, Pond's Seedling, Green Gage, Jefferson, Prince Englebert, Kirk's Blue Gage, Washington, Guthrie's Green Gage, Reine Claude de Bayay, one of the best dessert varieties grown; Automne Compote, Coe's Golden Drop, Goliath, and Washington. Plant the trees firmly, keep the base of the stem 6 inches distant from the wall, and spread the roots at various depths. If the roots when the trees reach their destination are dry, lay them in water for a few hours. Many failures are traceable to planting trees that have become unduly dry at the roots in transit. Correctly label each tree; and afford a mulch of straw stable manure. Newly-planted trees will require no further attention till spring, when (before finally nailing them to the walls), the mulching should be removed and the soil again trampled and smoothed over, leaving all tidy and neat.
